

Extraction tables

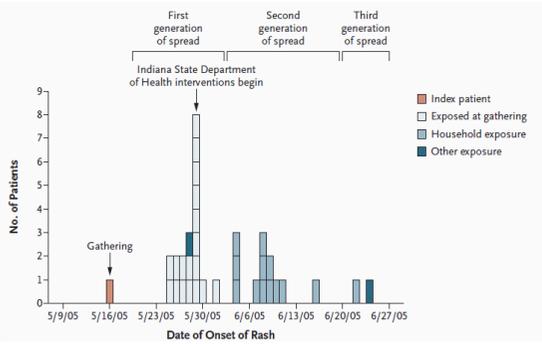

Systematic review on the incubation and infectiousness/shedding period of communicable diseases in children

Vaccine preventable diseases (n=19)

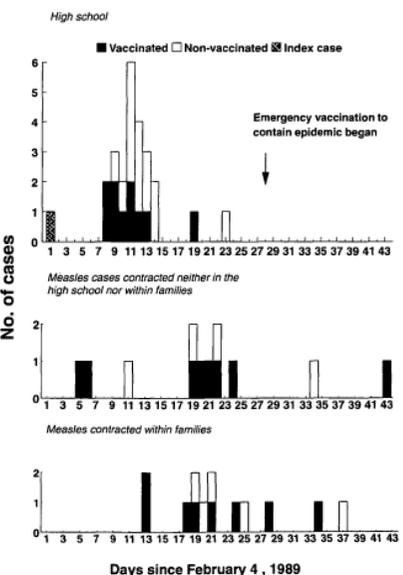

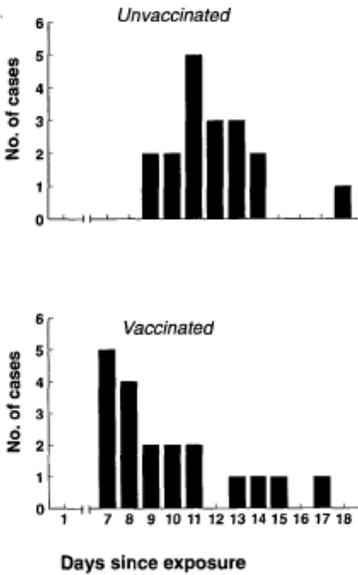

Measles (n=7)

Author, journal, year, aim	Country, study design, study period and duration	Setting, source population, in/exclusion criteria, sample size, age, gender	Disease/Infectious agent, case definition, sampling, laboratory-methods
<p>Author: Gahr</p> <p>Journal: Pediatrics</p> <p>Pub Year: 2014</p> <p>Aim: To determine the source, prevent transmission, and examine MMR-vaccine coverage in a community affected by a measles outbreak.</p>	<p>Country: United States</p> <p>Study design: Outbreak investigation</p> <p>Study period & duration: February 15 to April 24, 2011</p>	<p>Setting: Community and two homeless shelters</p> <p>Source population: Residents of Hennepin County</p> <p>Sample: *n=21 cases; of 1 index case and 20 community cases; of the community cases 17/20 were unvaccinated (2/20 unknown vaccination status, 1/20 vaccinated); of the unvaccinated cases 16/17 had a known exposure (serial interval presented for this group) *Age among the 16 unvaccinated cases with known exposure: 4 months to 4 yrs; median age: 17 months *Gender: NR</p>	<p>Disease/infectious agent: Measles</p> <p>Case definition: *2010 Council of State and Territorial Epidemiologists clinical case definition for measles: fever $\geq 38.8^{\circ}\text{C}$, generalized maculopapular rash lasting ≥ 3 days, and at least 1 of cough, coryza, or conjunctivitis; and *Laboratory confirmed, or epidemiological link to laboratory-confirmed case</p> <p>Sampling (specimen, frequency, duration): *Serology *NA</p> <p>Lab Method: Serology (positive measles-IgM or ≥ 4-fold rise in measles IgG), measles virus isolated in culture, or a positive reverse-transcriptase PCR</p>
Outcome definition, results			Comments, limitations
<p>Outcome definition: Serial interval: Time from rash onset case in a case and its secondary case</p> <p>Results: Serial interval: *Range: 5-32 days *Median: 13.5 days (Data extracted from figure by Pallas)</p>	<p>*Figure. Confirmed measles cases by exposure site and rash onset date</p>		<p>Comments: NR</p> <p>Limitations: *Serial interval, not incubation period</p>
<p>Ig: immunoglobulin; MMR: measles-mumps-rubella; NR: not reported; PCR: polymerase chain reaction; yrs: years</p>			

Author, journal, year, aim	Country, study design, study period and duration	Setting, source population , in/exclusion criteria, sample size, age, gender	Disease/Infectious agent, case definition, sampling, laboratory-methods
<p>Author: Lempriere Journal: BMJ Pub Year: 1931 Aim: To describe some unusual features of a small epidemic.</p>	<p>Country: NR, appears to be England Study design: Outbreak investigation Study period & duration: May 3 to June 28, 1930</p>	<p>Setting: School Source population: Pupils of Haileybury College Inclusion criteria: *Developed measles during the outbreak at the school Sample: *n=530 pupils in a school, among whom, n=115 were not protected by a previous measles attack, n=14 cases; incubation period based on 12 cases (first and last cases excluded from analysis because of uncertain incubation period) *Age NR, all pupils *Gender: NR</p>	<p>Disease/infectious agent: Measles Case definition: *NR, but based on symptoms. Sampling (specimen, frequency, duration): *NA Lab Method: NA</p>
Outcome definition, results			Comments, limitations
<p>Outcome definition: Incubation period: NR, probably intervals between exposure and the onset of symptoms</p> <p>Results: *Range: 10-20 days *Average: 16 days *Median: 17 days</p> <p>Exclusion period: Known contacts excluded for 10 days (6th-16th day after exposure). Based on the symptoms (well-marked rash and profuse Koplik's spots) of the first cases</p> <p>Children with whom the first case had been in contact and who had not had measles previously were excluded for 10 days, from the 6th to the 16th day after exposure.</p> <p>Results: Failed, the infection was still introduced in the school</p>			<p>Comments: *The author comments that the either Koplik's spots are not the absolute diagnostic sign of measles, as is generally held, or that under certain conditions the incubation period of measles may exceed a maximum of 16 days. In the author's experience the long incubation period is unique</p> <p>Limitations: *Very short report *Case definition is unclear *No laboratory confirmation</p>
NR: not reported			

Author, journal, year, aim	Country, study design, study period and duration	Setting, source population , in/exclusion criteria, sample size, age, gender	Disease/Infectious agent, case definition, sampling, laboratory-methods
<p>Author: Parker</p> <p>Journal: New Eng J Med</p> <p>Pub Year: 2006</p> <p>Aim: To investigate transmission patterns, rates of vaccination coverage, and costs of containment activities related to the outbreak to determine whether new policies are needed to sustain the elimination of measles in the United States.</p>	<p>Country: United States</p> <p>Study design: Outbreak investigation</p> <p>Study period & duration: May 2 to July 8, 2005</p>	<p>Setting: Community</p> <p>Source population: People who attended a church gathering in Indiana and their community</p> <p>Inclusion criteria: *Measles infection *Incubation period only for those who attended gathering</p> <p>Sample: *Ca. 500 people attended a church gathering with the index case, of whom n=18 contracted measles (of whom 16 lacked evidence of measles immunity). During the entire outbreak, 34 people acquired measles. *88% of the 34 measles cases were <20 yrs *Gender: NR</p>	<p>Disease/infectious agent: Measles virus</p> <p>Case definition: *Symptoms or signs during the outbreak that were compatible with the standard clinical definition of a case of measles; or clinical symptoms and *Either laboratory-confirmed acute measles infection or epidemiologically linked to a patients with laboratory-confirmed measles infection</p> <p>Sampling (specimen, frequency, duration): *Serum or urine *NA</p> <p>Lab method: Serum: IgM EIA capture assay Urine: PCR</p>
Outcome definition, results			Comments, limitations
<p>Outcome definition: Incubation period: Time from exposure at gathering to day of onset of rash</p> <p>Results: Range: 9-16 days; mean: 12.1 days; median: 13 days (Calculated by Pallas, based on numbers read from figure by Pallas)</p>	<p>*Figure. Patients with measles, according to day of onset of rash</p>  <p>The figure is a bar chart titled 'Patients with measles, according to day of onset of rash'. The x-axis represents the 'Date of Onset of Rash' from 5/9/05 to 6/27/05. The y-axis represents the 'No. of Patients' from 0 to 9. The chart is divided into three generations of spread: First generation (5/16/05 to 5/30/05), Second generation (6/6/05 to 6/13/05), and Third generation (6/20/05 to 6/27/05). A 'Gathering' is marked on 5/16/05. 'Indiana State Department of Health interventions begin' is marked on 5/30/05. The legend indicates: Index patient (red), Exposed at gathering (white), Household exposure (light blue), and Other exposure (dark blue). The highest number of cases (8) occurred on 5/30/05, primarily due to exposure at the gathering.</p>		<p>Comments: NR</p> <p>Limitations: *Some mixed data: 2/18 people that acquired measles at the gathering had evidence of measles immunity; and 12% of all people that acquired measles during the entire outbreak (including secondary cases) were ≥20 yrs of age</p>
<p>IgM EIA: immunoglobulin M enzyme immunoassay; NA: not applicable; NR: not reported; PCR: polymerase chain reaction; yrs: years</p>			

Author, journal, year, aim	Country, study design, study period and duration	Setting, source population , in/exclusion criteria, sample size, age, gender	Disease/Infectious agent, case definition, sampling, laboratory-methods
<p>Author: Paunio</p> <p>Journal: Am J Epidemiol</p> <p>Pub Year: 1997</p> <p>Aim: To examine whether differences in measles inoculum intensity affected measles risk among vaccinees and whether properly vaccinated measles patients became contagious during an explosive school outbreak in a small rural Finnish municipality in 1989.</p>	<p>Country: Finland</p> <p>Study design: Outbreak investigation</p> <p>Study period & duration: 1989 (the outbreak was contained within 3 weeks)</p>	<p>Setting: High school</p> <p>Source population: High school in Honkajoki, a small agricultural municipality in south-western Finland (three junior classes, n=76, aged 13-15 yrs and three senior classes n=68, aged 16-18 yrs)</p> <p>Inclusion criteria: *For high school students: measles cases exposed to the index case on February 4, 1989 *For secondary cases: symptoms and signs commenced 7-18 days after onset of symptoms in another case in the same household</p> <p>Sample: *n= 51 measles patients (of which 34 laboratory-confirmed); n=25 cases in high school (of which 22 infected in one day), and n=15 secondary cases within families *Age of the 22 school cases: 13-15 yrs: n=21; 16-18 yrs: n=1; age of secondary cases: children *Gender: NR</p>	<p>Disease/infectious agent: Measles</p> <p>Case definition: *Measles defined according to CDC criteria; however, date of disease onset was not based on onset of rash (nurse asked patients when they "came down with measles") *Primary cases: infected outside the home; secondary cases: infected at home by a sibling and symptoms and signs started 7-18 days after the onset of symptoms in another case in the household</p> <p>Sampling (specimen, frequency, duration): *Serum</p> <p>Lab Method: Serology</p>

Outcome definition, results			Comments, limitations
<p>Outcome definition: Incubation period: 1) For high school students with measles: number of days since exposure to index case on February 4, 1989 until student "came down with measles" (the authors note the index case likely infected 22 students in one day) 2) For high school students with measles and for the secondary cases in the family: number of days since exposure</p> <p>Results: 1) Incubation period among non-vaccinated high-school students with measles (n=13): Range: 9-14 days Median: 12 days 2) Incubation period among non-vaccinated high-school students with measles and non-vaccinated secondary cases (n=18): Range: 9-18 days Median: 11.5 days (Calculated by Pallas based on numbers read from figures)</p>	<p>Figure. Course of measles outbreak in Honkajoki high school (on the x-axis days since February 4, 1989)</p> 	<p>Figure. Measles incubation periods in unvaccinated and vaccinated individuals</p> 	<p>Comments: *Incubation period in vaccinated high school students with measles (n=9): range 8-13, median 10. Incubation period in vaccinated high schools students with measles and secondary cases (n=19): range 7-17, median 10 days. *Vaccinees had an approximately 2 days shorter incubation time than unvaccinated persons (p<0.001). To the knowledge of the authors, It has not been previously suggested that the incubation period among vaccinees may be shorter than that among non-vaccinees; therefore, the found observation must be validated by additional studies *Vaccinated and unvaccinated students with measles were equally able to infect their siblings *The local outbreak of the present study was part of the last large outbreak season in Finland in 1988-1989, when 1,749 cases of measles were serologically confirmed. *Ventilation was particularly poor in the school hallway, where a daily student assembly was held</p> <p>Limitations: *Imprecise definition of measles onset (nurse asked each person who contracted measles the date on which he or she "came down with measles"); but this should have made the difference between the incubation periods of vaccinees and non-vaccinees weaker not created a difference *It is possible that vaccines in Honkajoki were exposed temporarily to heat exceeding 30°C for 15-30 minutes during local transportation; which might be a possible explanation the high risk of measles upon exposure among those who had received 2 or 3 doses of vaccine</p>
<p>NA: not applicable; NR: not reported; yrs: years</p>

Pertussis (n=2)

Author, journal, year, aim	Country, study design, study period and duration	Setting, source population, in/exclusion criteria, sample size, age, gender	Disease/Infectious agent, case definition, sampling, laboratory-methods																															
<p>Author: Kwantes</p> <p>Journal: J Hyg (Lond)</p> <p>Pub Year: 1983</p> <p>Aim: To report some of the factors influencing the isolation rate of <i>Bordetella pertussis</i> during a whooping cough epidemic in West Glamorgan, Wales</p>	<p>Country: Wales</p> <p>Study design: Outbreak monitoring study (population level)</p> <p>Study period & duration: November 1977 to early March 1979</p>	<p>Setting: General Practitioners</p> <p>Source population: Patients in West Glamorgan (population ± 360,000)</p> <p>GPs made telephone notifications of whooping cough to two laboratories. Nurses visited one of two laboratories daily to collect whooping cough investigation outfits, questionnaire forms and names and addresses of notified cases. If possible the household was visited that day, and a pernasal swab was taken from the notified case as well as from any other occupant with symptoms. A 2nd visit was made 2 weeks later to make further observations and take swabs from any secondary case. After 3 months nurses made a final call to study the outcome.</p> <p>Sample: *212 GPs, n=2,321 cases of clinical whooping cough (out of n=3148 notified cases) of which 905 laboratory-confirmed Vaccination status only reported among those <10 yrs: 1426 (77%) unvaccinated; 882/2,321 clinical and 330/905 lab confirmed cases did not receive antibiotics. *Age among clinical cases: <5yrs, n=1,505 (65%); <10 yrs, n=1,850 (80%); adults >20 yrs, n=235 (10%) *M/F-ratio among clinical cases: 48.3%/51.7%</p>	<p>Disease/infectious agent: <i>Bordetella pertussis</i></p> <p>Case definition: *Clinical whooping cough: notified cases who on clinical ground satisfied the diagnostic criteria for whooping cough</p> <p>Sampling (specimen, frequency, duration): *Pernasal swabs *Once (if possible on the date of case notification)</p> <p>Lab Method: Isolation from pernasal swabs and identification by neutralisation or immunofluorescent test</p>																															
Outcome definition, results		Comments, limitations																																
<p>Outcome definition: Duration of shedding: Percentage isolation rate among all clinical cases according to the number of weeks after illness onset</p> <p>Results: For those without vaccination and antibiotic treatment: ~40% isolation rate at week 1, 2 and 4, ~50% at week 2, ~20% after 6 weeks and ~10% after 7 weeks since illness onset (Numbers read from graph by Pallas)</p>	<p>Figure. Isolation rate according to the week of illness. ▲, All ill cases; ○, those not given an antibiotic and, ■, those who had not been vaccinated and were not given an antibiotic.</p>  <table border="1"> <caption>Approximate data from the graph</caption> <thead> <tr> <th>Week of illness</th> <th>All ill cases (▲)</th> <th>No antibiotic (○)</th> <th>No antibiotic, no vaccination (■)</th> </tr> </thead> <tbody> <tr> <td>1</td> <td>42</td> <td>40</td> <td>40</td> </tr> <tr> <td>2</td> <td>60</td> <td>50</td> <td>50</td> </tr> <tr> <td>3</td> <td>48</td> <td>40</td> <td>40</td> </tr> <tr> <td>4</td> <td>48</td> <td>42</td> <td>42</td> </tr> <tr> <td>5</td> <td>38</td> <td>28</td> <td>28</td> </tr> <tr> <td>6</td> <td>18</td> <td>15</td> <td>15</td> </tr> <tr> <td>7</td> <td>10</td> <td>8</td> <td>8</td> </tr> </tbody> </table>	Week of illness	All ill cases (▲)	No antibiotic (○)	No antibiotic, no vaccination (■)	1	42	40	40	2	60	50	50	3	48	40	40	4	48	42	42	5	38	28	28	6	18	15	15	7	10	8	8	<p>Comments: *Large outbreak following a period of very low immunisation rate *The isolation rates are based on parallel measurements at different disease stages; 887/905 lab confirmed cases had disease durations >3 weeks *The isolation rate by week of illness was reportedly not influenced by either vaccination state or antibiotic therapy, although two types of antibiotics were reported to significantly reduce the chance of isolation *The Department of Health and Social Security (1977) in their memorandum on the control of infectious diseases in schools, recommends a minimum period of exclusion from school of 21 days from onset of paroxysmal cough. In the present study 15-20% of patients were still found to be carrying <i>B. pertussis</i> at 6 weeks and according to the authors it is therefore questionable whether exclusion from school for 3 weeks is likely to have any significant effect in controlling an outbreak.</p> <p>Limitations: *Only one sample per person, but large study *Reliance on recall for onset of disease</p>

<p>Author: Stocks</p> <p>Journal: Lancet</p> <p>Pub Year: 1933</p> <p>Aim: To report additional observations on the sex- and age-incidence of whooping cough in London, its probable incubation period, its transmission in houses, streets and schools, and the measures which might prove efficacious in reducing its ravages.</p>	<p>Country: England</p> <p>Study design: Descriptive study of notified and reported pertussis cases in Greenwich 1919-29, Battersea 1925-30, Wandsworth 1926-28, and Holborn 1921-28</p> <p>Study period & duration: 1919-1928 (Greenwich 1919-29, Battersea 1925-30, Wandsworth 1926-28, and Holborn 1921-28)</p>	<p>Setting: Community (house-, family, street- and school-level)</p> <p>Source population: London areas (Greenwich, Battersea, Wandsworth, and Holborn)</p> <p>Inclusion criteria: *Notified and reported cases of whooping cough in Greenwich 1919-29, Baattersea 1925-30, Wandsworth 1926-28, and Holborn 1921-28</p> <p>Sample: *n=15,283 cases *Age: 0yrs, n=1657; 1yr, n=1708; 2yrs, n=1713; 3yrs, n=2036; 4yrs, n=2377; 5yrs, n=2871; 6yrs, n=1656; 7yrs, n=584; 8yrs, n=228; 9yrs, n=114; 10-15yrs, n=225; 15+yrs, n=114 for the 4 areas; incubation period was based on a subset: household data from Battersea and Greenwich *M/F-ratio: 7263/8020</p>	<p>Disease/infectious agent: <i>Haemophilus pertussis</i></p> <p>Case definition: *Notified and reported cases</p> <p>Sampling (specimen, frequency, duration): *Cough sample *NA</p> <p>Lab Method: Bacterial cultures; Plates of a special medium of potato, horse blood and agar were held at 6 inches from whooping-cough patients whilst coughing</p>
Outcome definition, results			Comments, limitations
<p>Outcome definition: Incubation period: NR</p> <p>Results: From the form of the curve the authors conclude that it is possible for the incubation period to be as short even as 3 days, but it will most probably be a week. The upper limit cannot be determined from this data since it is not known how long after onset the infection was conveyed to the second child</p>	<p>*Figure. Frequency distribution of intervals between onset of successive cases of whooping cough</p> 	<p>Comments: *Children with short interval between them may infected from the same outside source on different days or one from the other within the house; However, the author believes from form of the curve in the figure that direct infections with intervals as short as 2 days are possible and that almost all intervals of 4 days or more may be attributed to direct infection of the second child by the first *The author notes that owing to the greater danger of whooping cough to young (pre-school) age children, control measures should seek to protect this group from infection by school children. It is therefore speculated, that the value of excluding from infected school home contacts to whooping cough cases is questionable and that it would probably be better to keep these children at school until the first signs of catarrh or cough (the most infectious period precedes the onset of the whoop); and that isolation of cases within the home would be worthwhile.</p> <p>Limitations: *Case definition is unclear *Incubation period is based on speculations in the light of the recorded serial intervals. *No right tail data *Difficult to read"</p>

Rubella (n=2)

Author, journal, year, aim	Country, study design, study period and duration	Setting, source population, in/exclusion criteria, sample size, age, gender	Disease/Infectious agent, case definition, sampling, laboratory-methods
<p>Author: Sever</p> <p>Journal: JAMA</p> <p>Pub Year: 1965</p> <p>Aim: To report on the clinical and laboratory finding of the outbreak of rubella on St. Paul Island in Alaska.</p>	<p>Country: United States</p> <p>Study design: Household study</p> <p>Study period & duration: 5-17 June, 1963 and one follow-up in September 1963</p>	<p>Setting: Households</p> <p>Source population: Children from 14 household who lived on St. Paul Island (Pribilofs, Alaska) during a rubella epidemic in June 1963</p> <p>Inclusion criteria: Children <19 yrs, examined daily by one physician during the 13 day study period. None of the children had antibody initially, but antibody developed in all by the time the final blood samples were obtained.</p> <p>Sample: *n=46 children, n=45 developed symptoms of rubella (60% developed clinical rubella and 40% had enlarged nodes only). First isolation of virus from throat based on patients with prior negative sampling and last isolation of virus from throat based on patients with subsequent negative sampling or virus still be shed on final day of sampling, NR how many patients this concerns. *Age range among all children: 0-19 yrs; 0-4 yrs, n=4; 5-9yrs, n=13; 10-14yrs, n=16; 15-19yrs, n=13 *M/F-ratio: 23/23</p>	<p>Disease/infectious agent: Rubella</p> <p>Case definition: NR (60% had clinical rubella with both rash and characteristic posterior auricular or suboccipital lymph nodes; 40% had enlarged nodes only; 1 had none of these findings; none of the patients had antibody initially but all did by the time the final blood samples were obtained)</p> <p>Sampling (specimen, frequency, duration): *Throat swab specimens *Obtained daily from June 5-17 *Blood specimens *Obtained on June 5, 17 and September 29 or 30</p> <p>Lab Method: *Throat swab specimens tested for rubella using the enterovirus interference method. *Serum specimens used to detect neutralizing antibody by employing primary African green monkey-kidney roller-tube cultures.</p>
Outcome definition, results			Comments, limitations
<p>Outcome definition: Duration of shedding: Numbers of days from onset of rash to first or last isolation of virus from throat</p> <p>Results: *For patients with both rash and enlarged lymph nodes: virus was first isolated from the nasopharynx as early as 13 days before rash; in 5 days before the rash in the majority of cases; 2 days before the rash in all cases. The virus persisted for at least 2 days following rash and in one case was still present 6 days later when sampling ended. *It is not possible to determine the total duration of persistence of virus in all cases because intensive sampling was confined to a 13-day period, but virus was detected in throat specimens for 9 days in individuals with rash and nodes and 4 days in patients with nodes only (Numbers read from figure by Pallas)</p>			<p>*Figure. Clinical and laboratory findings in patients with rash and nodes (NB: graph 2 and 3 of interest)</p>  <p>1. DEVELOPMENT OF ANTIBODY Total of 27 patients, no antibody recorded for 1 patient.</p> <p>2. FIRST ISOLATION OF VIRUS FROM THROAT Including only patients with prior negative sampling.</p> <p>3. LAST ISOLATION OF VIRUS FROM THROAT Including patients with subsequent negative sampling or virus still being shed * on final day of sampling.</p> <p>4. ONSET OF NODES One patient with rash and no nodes.</p>
<p>M/F-ratio: male-to-female ratio; NR: not reported; yrs: years</p>			<p>Comments: *In total, the island had 357 native inhabitants *The authors expect the present study to provide a more accurate representation of the natural disease in a civilian population, since experimental rubella is atypical in that it has a relatively short incubation time (12 days) *The authors report that the incubation period during the epidemic on the island was approximately 16 days; definition and sample size are NR *A large portion of the children did not show rash and were relatively asymptomatic ("clinically inapparent rubella"); results for these children are therefore not presented here *Adenopathy occurred as early as 3 weeks before rash; however, the majority of patients had onset of nodes 1-2 weeks before the rash, and all patients had adenopathy by the day before the rash</p> <p>Limitations: *Intensive sampling was confined to a 13 day period and thus clinical and microbiological data was not complete</p>

Author, journal, year, aim	Country, study design, study period and duration	Setting, source population , in/exclusion criteria, sample size, age, gender	Disease/Infectious agent, case definition, sampling, laboratory-methods
<p>Author: Zhao</p> <p>Journal: Zhonghua Liu Xing Bing Xue Za Zhi</p> <p>Pub Year: 1992</p> <p>Aim: An epidemiological and serological investigation of a rubella outbreak associated with a cinema occurred in 4 primary schools.</p>	<p>Country: China</p> <p>Study design: Outbreak investigation</p> <p>Study period & duration: December 20, 1989 to February 12, 1990</p>	<p>Setting: Primary schools</p> <p>Source population: Primary school students (grade 3-6) in 3 counties in China who went to a cinema during 20 December, 1989-12 February, 1990</p> <p>Inclusion criteria: *Visited the cinema *Developed rubella</p> <p>Sample: *n=393, incubation period was based on n=169 first generation cases *Age range: 6-15 yrs *M/F-ratio: 186/207</p>	<p>Disease/infectious agent: Rubella</p> <p>Case definition: *NR, but probably based on symptoms such as fever and rash; sometimes also on laboratory-confirmation</p> <p>Sampling (specimen, frequency, duration): *Blood *NA</p> <p>Lab Method: ELISA to test rubella-specific IgM and IgG</p>
Outcome definition, results			Comments, limitations
<p>Outcome definition: Incubation period: Probably intervals between exposure (the day of visiting the cinema) and the onset of symptoms</p> <p>Results: *Range: 13-24 days *Mean: 17.8 days</p>			<p>Comments: *Among 53 cases, 33 were IgM positive; among 7 IgM negatives, all were IgG positive > 4 titres.</p> <p>Limitations: NR</p>
<p>ELISA: enzyme-linked immunoassay; Ig: immunoglobulin; NA: not applicable; NR: not reported; yrs: years</p>			

Varicella (n=6)

Author, journal, year, aim	Country, study design, study period and duration	Setting, source population, in/exclusion criteria, sample size, age, gender	Disease/Infectious agent, case definition, sampling, laboratory-methods
<p>Author: Asano</p> <p>Journal: J Ped</p> <p>Pub Year: 1985</p> <p>Aim: To describe the successful isolation of varicella zoster virus from the mononucleocytes during the incubation period of varicella in healthy children.</p>	<p>Country: Japan</p> <p>Study design: Household study</p> <p>Study period & duration: 4-month period in 1984</p>	<p>Setting: Hospital, households</p> <p>Source population: Susceptible children in households of children with onset of varicella visiting the pediatric outpatient clinic (one child who had close contacts with schoolmates with varicella was also included).</p> <p>Inclusion criteria: *No history of varicella. *Lives in household with child with varicella</p> <p>Sample: *n=12/12 children developed varicella, of whom n=11 were exposed in a family setting (and 1 in school setting) *Mean (\pm SD) age among all cases: 3.2 (\pm 1.8) yrs; range: 1-6 yrs *M/F-ratio among all cases: 8/4</p>	<p>Disease/infectious agent: Varicella</p> <p>Case definition: *NR, the 12 cases had typical manifestation of the disease with vesicular rashes; or clinical symptoms and *Laboratory-confirmation</p> <p>Sampling (specimen, frequency, duration): *NA</p> <p>Lab Method: Virus isolates identified by characteristic cytopathic effect to VZV</p>
Outcome definition, results			Comments, limitations
<p>Outcome definition: Incubation period/Serial interval: Interval between onset of vascular rash in the index case and onset of exanthema in the contact</p> <p>Results: *Among family contacts (n=11): Range: 13-18 days Mean (\pm SD): 14.0 \pm 1.4 days</p>			<p>Comments: *The serial interval in the 1 child who was exposed in school was 20 days</p> <p>Limitations: *Based on table headings, the period appears to be an incubation period, i.e. was calculated from moment of exposure ('contact') (day of sampling after contact + day of onset of disease after sampling); however in the text, it appears to be a serial interval, i.e. see outcome definition</p>
<p>M/F-ratio: male-to-female ratio; NR: not reported; SD: standard deviation; VZV: varicella zoster virus; yrs: years</p>			

Author, journal, year, aim	Country, study design, study period and duration	Setting, source population, in/exclusion criteria, sample size, age, gender	Disease/Infectious agent, case definition, sampling, laboratory-methods
<p>Author: Gordon</p> <p>Journal: JAMA</p> <p>Pub Year: 1929</p> <p>Aim: To assess the incubation time and period of infectivity in a group under strict isolation and simultaneously infected with scarlet fever.</p>	<p>Country: NR, appears to be United States</p> <p>Study design: Outbreak investigation</p> <p>Study period & duration: NR</p>	<p>Setting: Hospital</p> <p>Source population: Children in scarlet fever wards who had been under strict isolation for twenty-one days previous to exposure to chicken-pox</p> <p>Inclusion criteria: *In scarlet fever ward *For serial interval: only secondary cases were included</p> <p>Exclusion criteria: *For serial interval: tertiary or later cases were excluded because they were not subject to the same controlled circumstances</p> <p>Sample: *Serial interval based on n=67 cases; n for period of infectiousness before eruptions NR; period of infectiousness after eruptions based on 4 cases and 21 non-immune contacts *Age: children *Gender: NR</p>	<p>Disease/infectious agent: Varicella</p> <p>Case definition: *NR, but in a hospital setting, eruptions were mentioned, thus probably based on classical symptoms such as eruptions.</p> <p>Sampling (specimen, frequency, duration): *NA</p> <p>Lab Method: NA</p>
Outcome definition, results			Comments, limitations
<p>Outcome definition: Serial interval: Intervals between eruptions in secondary cases and lesions appeared in the primary case</p> <p>Results: Range: 11-20 days Median: 15 days Infectivity preceding the eruptive stage must be of short duration.</p> <p>*A boy (age 6), was transferred from a large scarlet fever ward to a ward for convalescents. There had been no chickenpox in either ward for several months. A beginning chickenpox eruption was noted 25 hours after the transfer. In the original ward, with a population of boys aged from 4 to 10 years, there were 8 who had never had chickenpox and 8 others with a history of the disease. Boys in contiguous beds were nonimmune. No cases of chickenpox developed within the next 22 days. In the ward to which the boy was transferred, 3 secondary cases occurred. It would appear in this instance that varicella was not infectious 24 hours preceding the eruption.</p> <p>*A patient (age 4) was removed in the morning from a scarlet fever ward for a mastoid operation, and thereafter isolated in another unit. No patient in the original ward gave any evidence of an unusual skin eruption in the course of routine morning baths. In the afternoon, 1 had lesions of chickenpox. The girl removed about 9 hours previously for a mastoid operation developed varicella 17 days later.</p> <p>*In other instances, patients discharged from wards in which chickenpox later developed were investigated by the visiting nurse at their homes. 6 nonimmune patients discharged the day previous to the discovery of chickenpox, 4 2 days previously, 5 with an interval of 3 days and 8 with a 4 day interval, all reported that chickenpox did not occur subsequently.</p> <p>There is some reason to believe that contact infection of chickenpox ceases about the end of the first week of the eruption or the beginning of the second. Varicella certainly is infectious by contact on or before the 5th day.</p> <p>*4 different patients with both scarlet fever and chickenpox have been admitted through accident or error to scarlet fever wards. They represented varicella of 8, 11, 14 and 16 days' duration. All had crusted lesions. No secondary cases were noted among 21 nonimmune contacts</p>			<p>Comments: NR</p> <p>Limitations: *All cases were infected with scarlet fever and then got chickenpox *Serial interval, not incubation period (though if there has been a single exposure perhaps it is close to the incubation period)</p>
NR: not reported			

Author, journal, year, aim	Country, study design, study period and duration	Setting, source population, in/exclusion criteria, sample size, age, gender	Disease/Infectious agent, case definition, sampling, laboratory-methods
<p>Author: Ma</p> <p>Journal: MMWR</p> <p>Pub Year: 2006</p> <p>Aim: To identify factors contributing to the higher rate of transmission in an outbreak and to assess the effectiveness of control measures.</p>	<p>Country: China</p> <p>Study design: Outbreak investigation</p> <p>Study period & duration: January 1 to June 24, 2004</p>	<p>Setting: Primary school</p> <p>Source population: Students in classes with outbreak of varicella at a primary school in Beijing, China</p> <p>Inclusion criteria: *Students who did not have varicella before January 1, 2004 *Varicella infection</p> <p>Sample: *n=635 students in 15 classrooms from the 4 lowest grades, analysis limited to 488 (77%) students who did not have varicella before January 1, 2004. n=5 classrooms in which primary cases was isolated only after ≥ 2 days of rash (3 classrooms with single primary case, 2 classrooms with several co-primary cases) n=7 classrooms in which primary cases were isolated immediately n=3 classroom without cases *Age range in the 4 lowest grades: 3-8 yrs *Gender: NR</p>	<p>Disease/infectious agent: VZV</p> <p>Case definition: *Vesicular pruritic rash in a school student lasting >4 days with onset during January 1 to June 26, 2004.</p> <p>Sampling (specimen, frequency, duration): *NA</p> <p>Lab method: NA</p>
Outcome definition, results			Comments, limitations
<p>Exclusion period: School policy of 7 days isolation</p> <p>In this study the following were compared: classrooms where exclusion took place immediately when vesicular pruritic rash was detected vs. classrooms where exclusion took place after ≥ 2 days</p> <p>Outcome measure: attack rates (ARs) and secondary attack rates (SARs) for classrooms</p> <p>Results: ARs 2 distinct groups: *10 classrooms with ARs $<15\%$ *5 classrooms with substantially higher ARs (40%--80%). In all classrooms with ARs $>40\%$, ≥ 1 ill students had remained in school >2 days while ill with a rash (these classrooms had new teachers who were not familiar with the school's isolation policy).</p> <p>SARs *In the 5 classrooms in which the student with the primary case was isolated only after >2 days of rash, the SAR was 21% (34/163) compared with 1.7% (4/235) in the 7 classrooms in which the first student with varicella rash was isolated immediately, RR=10 (CI 3.7-29.0). *In 3 classrooms in which a single student with a primary case was not isolated, the SAR was 26% (29/111), RR=12 (CI 4.4-34.0) compared with those classes for which cases were isolated immediately. *In the 2 classrooms with several coprimary cases, the SAR was 9.6% (5/52) compared with the classrooms with only isolated cases, RR=5.2 (CI 1.5-19)</p>			<p>Comments: *The 5 classes in which a single student with a primary case was not isolated did not differ from other classrooms regarding crowding, availability of handwashing, activities involving close personal contact, or the sharing of items that might act as fomites (e.g. towels, eating utensils, and cups).</p> <p>Limitations: *Information on previous history of varicella disease subject to recall bias *Possibility that mild primary cases were not identified, which might explain the occurrence of co-primary cases in some classrooms. *Part of the study population was vaccinated against varicella, not taken into account in the analysis *Unclear whether exclusion policy in one class could have influenced occurrence of disease in another class</p>
ARs: attack rates; NA: not applicable; NR: not reported; RR: relative risk; SAR(s): secondary attack rate(s); VZV: varicella-zoster virus; yrs: years			

Author, journal, year, aim	Country, study design, study period and duration	Setting, source population , in/exclusion criteria, sample size, age, gender	Disease/Infectious agent, case definition, sampling, laboratory-methods
<p>Author: Moore</p> <p>Journal: Am J Epidemiol</p> <p>Pub Year: 1991</p> <p>Aim: To assess the effectiveness of the exclusion policy by evaluating the routes of chickenpox transmission in this outbreak.</p>	<p>Country: United States</p> <p>Study design: Outbreak investigation</p> <p>Study period & duration: October 5 to December 21, 1988</p>	<p>Setting: Schools</p> <p>Source population: 2 Ohio school with students in grades kindergarten through 12 (n=1,886). School A: elementary, junior high, high school (n= >1500) School B: kindergarten through grade 8 (n=300)</p> <p>Inclusion criteria: *Cases with chickenpox identified by the school nurse *Classrooms with at least 2 cases *Only cases and classrooms with cases occurring during 2 specific periods (October 5 to November 23 and November 28 to December 21, 1988)</p> <p>Sample: *n=215 cases in schools A and B *Age range: 4-18yrs *Gender: NR</p>	<p>Disease/infectious agent: Varicella</p> <p>Case definition: *Case defined as: Chickenpox identified by the school nurse occurring in any child from school A or B during the period from October 5 to December 21, 1988. *Case classified as occurring within one incubation period (12-17 days) after a day of exposure or at some other time after exposure Possible exposures were considered to occur on the day -before a classmate stayed home with chickenpox (prodromal) or -the day a classmate returned to school after having had chickenpox</p> <p>Sampling (specimen, frequency, duration): *NA</p> <p>Lab Method: NA</p>

Outcome definition, results	Comments, limitations
<p>Outcome definition: NA</p> <p>Results:</p> <p>*It was shown that cases were 3.6 (95% CI 2.4-5.4) times more likely to occur 12-17 days after exposure to a prodromal case child than at any other time. (Based on person-time analysis in kindergarten up to grade 4; 44 cases with onset during 1695 person-days of observation 12-17 days after a prodromal classmate and 35 cases with onset during 4817 other person-days of observation)</p> <p>*This was most pronounced in the early phase of the outbreak (RR 10.8 (95%CI 4.4-26.5)) than in the latter part of the outbreak (RR 1.9 (95%CI 1.1-3.2)).</p> <p>*Children exposed to a returning classmate were no more likely to have become a case 12-17 days later than at any other time (RR 0.9 (95%CI 0.5-1.5)). 15 children returned to class after <5 days of absence from school; there were no cases among their classmates 12-17 days after their return.</p> <p>*Risk of chickenpox 12-17 days after a prodromal classmate, returning classmate, both exposures, or neither exposure was calculated using incidence density ratios, it was found that incidence density ratio was 3.0 (95%CI 1.9-4.8) when the risk period was prodrome only, 0.8 (95%CI 0.3-1.9) for return only, and 3.8 (95%CI 1.9-7.4) (reference group: neither).</p> <p>Exclusion period: Children were required to stay home for 7 days from onset of symptoms or until all lesions were crusted (mean and median duration were 7 days, based on attendance records)</p> <p>Results:</p> <p>The incidence density was not higher in children exposed to cases returning to school or no exposure; also it was not higher after the return of 15 cases < 5 days (NR if lesions were crusted).</p> <p>From their analyses, the authors cannot tell the optimal time a child should be excluded from school. However, since most transmission occurred before exclusion, exclusion policies may have limited effect.</p>	<p>Comments:</p> <p>*The outbreak occurred despite adherence to the exclusion policy for 7 days after rash onset or until all lesions were crusted</p> <p>Limitations:</p> <p>*Several possible sources of misclassification:</p> <ul style="list-style-type: none"> -Limiting exposure definition to 1 day before rash onset may lead to underestimation of transmission during prodrome -Exact exposure time/place was not fully certain -Incubation times could have been longer than the interval used (12-17 days)
<p>CI: confidence interval; NA: not applicable; NR: not reported; yrs: years</p>

<p>Author: Poulsen</p> <p>Journal: <i>Pediatr Infect Dis J</i></p> <p>Pub Year: 2005</p> <p>Aim: To describe the epidemiology and risk factors for severe chickenpox in Guinea-Bissau.</p>	<p>Country: Guinea-Bissau</p> <p>Study design: Prospective household study</p> <p>Study period & duration: April 2000 to December 2001</p>	<p>Setting: Households</p> <p>Source population: All households in 4 peri-urban districts</p> <p>Inclusion criteria: *Children with definite or possible chickenpox or herpes zoster detected via an existing surveillance system</p> <p>Sample: *n=1,539 cases (976 primary, 461 secondary, 88 tertiary and 14 quaternary cases) *Boys: median age 4.3 yrs (IQR 1.9; 6.5); Girls: median age 4.5 yrs (IQR 2.3; 7.0) (p<0.02). 4% is >15yrs *M/F-ratio: 49%/51%</p>	<p>Disease/infectious agent: Varicella</p> <p>Case definition: *Varicella diagnosis after clinical diagnosis and interview; or clinical symptoms and *Laboratory confirmation (in subgroup) **Primary cases: infected outside the home with no confirmed cases in the house during the incubation period. **Secondary cases: cases occurring within 10-29 days after the first case in the house (based on their distributions, where the likely minimum interval was estimated at 10 days) *Co-index case (presumably infected outside the home): cases occurring after the first case but with an interval of less than the likely minimum interval</p> <p>Sampling (specimen, frequency, duration): *Blood samples (from a subgroup only) *NA</p> <p>Lab Method: Indirect enzyme-linked immunosorbent assay</p>
Outcome definition, results			Comments, limitations
<p>Outcome definition: Serial interval: Period between the onset of rash in the index case and onset of rash in the secondary case. If more than one possible index case existed, the individual with closest contact was chosen.</p> <p>Results: Compared with sleeping in the same bed, the serial interval was significantly longer both within the household or when the index case was in another household but in the same house (respectively, 15.2 days (95% CI 14.6-15.7) for exposure in the same bed, 15.9 days (95% CI 15.2-16.6) for exposure in the same room, 16.1 (95% CI 15.4-16.9) for exposure in the same household and 16.5 days (95% CI 16.0-17.1) for cases exposed from another household, p<0.01 controlled for age and gender)</p>			<p>Comments: *The length of the serial interval depends on intensity of exposure, suggesting that the dose of infection might be important. The intensity of contact may therefore also influence severity of infection *Treatment was given if necessary. Treatment was not further described but may apply to complications such as pneumonia</p> <p>Limitations: *Serial interval, not incubation period</p>
<p>CI: confidence interval; IQR: interquartile range; M/F-ratio: male-to-female ratio; NA: not applicable; yrs: years</p>

Country: United States Study design: Outbreak investigation Study period & duration: Exposed on June 21. Follow-up till June 30, 2004	Setting: School-organized trip to Mexico Source population: Participants of a school-organized trip to Mexico Inclusion criteria: *Detection of an enterovirus Exclusion criteria: *Travelers with illness onset \geq 27 June Sample: *n=29 travellers, of whom n=12 became ill *Age of all travellers: teenagers: n=25; and adults: n=4 *Gender: NR	Disease/infectious agent: Echovirus-30 Source: The Gulf of Mexico Case definition: *Acute illness: headache, vomiting, diarrhea *EV identified in stools or cerebrospinal fluid Sampling (specimen, frequency, duration) *Stools or cerebrospinal fluid *NA Lab method: Culture, NASBA and EV VP1

Outcome definition, results

Outcome definition:
 Incubation period: Days between swimming in Gulf of Mexico and onset of illness

Results:
 Exposure 4 days before primary illness peak

Figure. Summary of laboratory testing results and illness status for the travellers.
 CV: coxsackievirus, E30: echovirus 30, NEG: negative.

EV: enterovirus; EV-30: echovirus-30; NASBA: nucleic acid sequence-based amplification; NR: not reported; RT-snPCR: real-time semi-nested polymerase chain reaction

Gastroenteritis by adenovirus (n=2)

Author, journal, year, aim	Country, study design, study period and duration	Setting, source population , in/exclusion criteria, sample size, age, gender	Disease/Infectious agent, case definition, sampling, laboratory-methods
<p>Author: Uhnoo</p> <p>Journal: J Clin Microbiol</p> <p>Pub Year: 1984</p> <p>Aim: To describe the clinical features of Ad40 and Ad41 in comparison with the established adenoviruses.</p>	<p>Country: Sweden</p> <p>Study design: Case series</p> <p>Study period & duration: January-December 1981</p>	<p>Setting: Hospital</p> <p>Source population: Children <15 years of age who directly sought medical advice at the Department of Pediatrics of the University Hospital of Uppsala during the study period, or for whom there was telephone consultation.</p> <p>Inclusion criteria: *Acute gastroenteritis *Stool samples available</p> <p>Sample: *n=416 ill children, n=48 had evidence of enteric adenoviruses (enteric adenoviruses (Ad40, Ad41) were found as the sole recognizable cause of diarrhea in n=30; as part of a dual infection in n=3; and established adenovirus (known non-Ad40/Ad41-adenoviruses) in n=15), n=37 with stool samples from the convalescent phase (n=26 with enteric adenoviruses infection and n=11 patients with established adenovirus infections) *Age range among all ill children: 3 weeks-13 years. 38% <1 yr; 33% 1-2 yrs; 19% 2-5 yrs; 10% >5 yrs *M/F-ratio among all ill children: 55%/45%</p>	<p>Disease/infectious agent: Adenovirus (Ad40 and Ad41, and other previously established adenoviruses (including Ad40, Ad41, Ad7, Ad18, Ad31))</p> <p>Case definition: *Acute gastroenteritis; and *Laboratory confirmed adenovirus infection (detection in stools or seroconversions)</p> <p>Sampling (specimen, frequency, duration): *Stools; obtained from all patients as soon as possible after admission to the hospital, and from 1/3rd also at a later stage. *Blood; paired acute and convalescent-phase serum specimens were available from 50% of the patients.</p> <p>Lab Method: All stool specimens were examined by EM. Stool suspensions were prepared and cultured for virus isolation. Viral DNA was analyzed by restriction endonuclease. A genus-specific ELISA detected all adenovirus and a species-specific ELISA detected Ad40. Complement fixation (CF) test, hemagglutination inhibition (HI) assay, and ELISA were used for adenovirus antibodies.</p>
Outcome definition, results		Comments, limitations	
<p>Outcome definition: Duration of shedding: Duration that adenoviruses could be observed after onset of disease</p> <p>Results: *From 26 patients with EAd40 or EAd41 infections and 11 established adenovirus infections: no viral particles were observed 4-6 weeks after the onset of the diarrheal illness *In 9/10 patients studied, EAds were excreted in stool samples up to 8-13 days after the onset of disease, in the remaining patient virus was demonstrable for 23 days</p>		<p>Comments: *Nearly all patients had diarrhea, followed by vomiting, fever, abdominal pain, dehydration and respiratory symptoms *Prolonged diarrhea was common *EAds refer to previously (=in 1975) unrecognized adenoviruses that were detected by electron microscopy in stool specimens from infants with diarrhea. The two distinct species of EAds that have now been identified (=1981) are Ad40 and 41; they represent two new subgenera, F and G, respectively.</p> <p>Limitations: *Unclear reporting of shedding, it is possible that the data on shedding (8-23 days) is based on only one stool sample per person</p>	
<p>Ad40: adenovirus 40; EAds: enteric adenoviruses (i.e. Ad40, Ad41); ELISA: enzyme-linked immunosorbent assay; yrs: years</p>			

Author, journal, year, aim	Country, study design, study period and duration	Setting, source population, in/exclusion criteria, sample size, age, gender	Disease/Infectious agent, case definition, sampling, laboratory-methods
<p>Author: Van</p> <p>Journal: J Pediatr</p> <p>Pub Year: 1992</p> <p>Aim: To evaluate enteric adenovirus (EAd) as a cause of outbreaks of diarrhea among infants and toddlers in day care centers.</p>	<p>Country: United States</p> <p>Study design: Prospective surveillance study</p> <p>Study period & duration: January, 1986-March, 1987; December 1987-April 1988; January to March 1989; October 1989-December 1991</p>	<p>Setting: Day care centers</p> <p>Source population: Children <24 months who were enrolled in 17 DCCs, in Texas</p> <p>Inclusion criteria:</p> <p>*During each study period, children up to and including 24 months of age who were newly enrolled in the DCCs were enrolled in the study. Stool specimens were collected regardless of symptoms.</p> <p>Sample:</p> <p>*n=249 children exposed, of whom n=94 children had laboratory-confirmed EAd infection, of whom n=51 had diarrhea (and n=43 were well)</p> <p>*Age range: 1-24 months</p> <p>*Gender: NR</p>	<p>Disease/infectious agent: Enteric Adenovirus types 40 and 41</p> <p>Case definition:</p> <p>*Diarrhea (passage of unformed stools with at least twice the usual daily frequency); and</p> <p>*Detection of EAd in a stool specimen</p> <p>Sampling (specimen, frequency, duration):</p> <p>*Stools</p> <p>*Collected weekly during study period</p> <p>*When diarrhea was identified, stools were collected twice weekly</p> <p>Lab Method:</p> <p>*Children with diarrhea had a stool tested for <i>Shigella</i>, <i>Salmonella</i>, <i>Campylobacter jejuni</i>, <i>Aeromonas</i>, <i>Yersinia enterocolitica</i>, <i>Plesiomonas</i>, and <i>Escherichia coli</i> O157:H7 by standard laboratory microbiologic procedures.</p> <p>*Enzyme immunoassay methods were used to detect EAd, group A rotavirus and <i>Giardia lamblia</i> antigens.</p> <p>*Testing of EAd with the Adenoclone 40/41 EIA was performed.</p>
Outcome definition, results			Comments, limitations
<p>Outcome definition:</p> <p>Duration of shedding: Total duration (i.e. including time before onset of symptoms) EAd was found in the stools</p> <p>Results:</p> <p>*Among children with a symptomatic infection: mean duration of total excretion (i.e. including time before onset of symptoms): 4.2 (\pm 0.4) days</p> <p>*9 children excreted EAd before diarrhea occurred (range: 1-7 days, mean: 2.6 days)</p> <p>*10 children excreted EAd after diarrhea stopped (range: 1-11 days; mean: 5.3 days)</p> <p>*4 children were intermittent excreters (i.e. they formed stools without detectable EAd in between watery stools in which EAd was detected)</p>			<p>Comments:</p> <p>*For study period 1, only outbreaks without a known cause were evaluated for EAd</p> <p>*The mean total duration of excretion among asymptomatic children was 2.8 (\pm 0.5) days. This was significantly shorter than in children with symptoms ($p=0.04$).</p> <p>*Overall the mean total duration of EAd excretion by children (regardless of symptoms) was 3.9 days (range: 1-14 days)</p> <p>Limitations:</p> <p>*Duration of shedding not given by number of days since onset of symptoms</p>
DCCs: day care centres; EAd: enteric adenovirus			

Gastroenteritis by astrovirus (n=3)

Author, journal, year, aim	Country, study design, study period and duration	Setting, source population, in/exclusion criteria, sample size, age, gender	Disease/Infectious agent, case definition, sampling, laboratory-methods																														
<p>Author: Cruz</p> <p>Journal: J Clin Microbiol</p> <p>Pub Year: 1992</p> <p>Aim: To report the observations regarding astrovirus infections and diarrhea among rural ambulatory children under 3 years of age, living in a rural community of Guatemala.</p>	<p>Country: Republic of Guatemala</p> <p>Study design: Prospective observational study</p> <p>Study period & duration: February 1987 to February 1989</p>	<p>Setting: Rural village in the highlands</p> <p>Source population: Children from different families, living in Santa María de Jesús</p> <p>Inclusion criteria: *Detection of astrovirus</p> <p>Sample: *n=321 children enrolled in the study of whom n=124 (38.6%) excreted astrovirus *Age of all cases: 0-3 months *Gender of all cases: 51.4% males</p>	<p>Disease/infectious agent: Astrovirus</p> <p>Case definition: *Diarrhea episode; and *Astrovirus-positive sample</p> <p>Sampling (specimen, frequency, duration): *Stools *Routine stools once a month. During episode of diarrhea, every other day. If the episode last >6 days, additional samples taken weekly and during convalescence *Sampling till 7 days after the episode was over (72 continuous hours without symptoms). Children were followed until they reached their third birthday or for the duration of the study</p> <p>Lab method: ELISA</p>

Author, journal, year, aim	Country, study design, study period and duration	Setting, source population , in/exclusion criteria, sample size, age, gender	Disease/Infectious agent, case definition, sampling, laboratory-methods
Author: Esahli Journal: Pediatr Infect Dis J Pub Year: 1991 Aim: To assess the role of astrovirus as an etiologic agent of nosocomial and community-acquired gastroenteritis and to investigate the clinical features, epidemiology and pattern of nosocomial spread in two outbreaks.	Country: Sweden Study design: Case series Study period & duration: September 1987-December 1988	Setting: Hospital Source population: Hospitalized children at St. Goran's Children's Hospital, Stockholm Inclusion criteria: *Nosocomial diarrhea *Astrovirus was identified Sample: *n=32 cases with nosocomial astrovirus infection: incubation period was estimated based on 24/32 cases; 20/32 patients had repeated stool samples, of which n=18 were symptomatic and n=8 were symptomatic and had ≥3 stool samples *Age among all nosocomial astrovirus cases: <1yr, n=28; 1-2 yrs, n=4 *M/F-ratio among all nosocomial astrovirus cases: 12/20	Disease/infectious agent: Astrovirus Source: Nosocomial infection Case definition: *Nosocomial gastroenteritis (gastroenteritis defined as nosocomial when onset of diarrhea and/or vomiting began ≥72 hours after admission or <72 hours after discharge; diarrhea defined as an increase in frequency to >2 per 24 hours and/or a change in consistency of stool); and *Identification of astrovirus in stool Sampling (specimen, frequency, duration): *Stool *Every 3 to 4 days for 2 weeks Lab Method: Electron microscopy of stool samples. Virus isolation was performed on all cases in which no agent was identified by electron microscopy, primarily to detect nonenteric adenoviruses and enteroviruses.

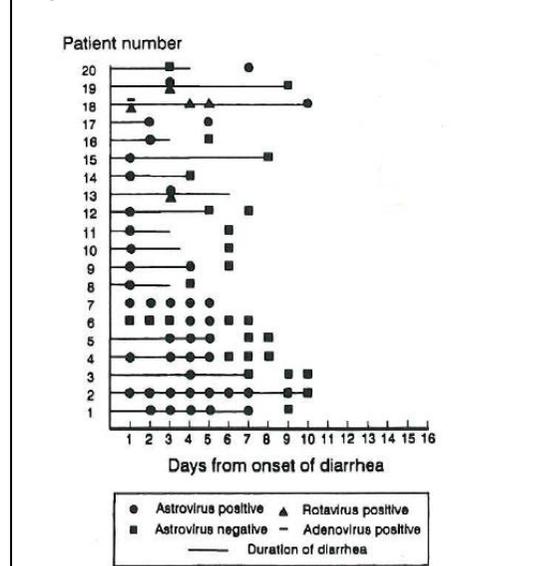

Outcome definition, results	Comments, limitations
-----------------------------	-----------------------

Outcome definition:
 *Serial interval: The interval between index case and secondary episodes
 *Duration of shedding: Number of days astrovirus could be identified in stools from onset of diarrhea

Results:
 Serial interval:
 *Range: 2-13 days
 *Mean: 3 days

Duration of shedding:
 *Among all symptomatic cases (n=18): range: 1-10 days after onset of diarrhea, median: 3.5 days after onset of diarrhea (calculated by Pallas, based on number read from graph)
 *Among all symptomatic cases with at ≥3 samples (n=8): range: 1-10 days after onset of diarrhea; median: 5 days after onset of diarrhea

*Figure. Duration of diarrhea and stool virus detection

in 20 cases of nosocomial astrovirus infection

Comments:
 *Rotavirus was found in 4/32 children and adenovirus was found in 1/32 child
 *30 children had diarrhea, 21 had vomiting, 10 had fever, 7 had respiratory symptoms, 5 had dehydration and 4 had metabolic acidosis
 *Of the 32 children, 19 children were treated with diet modification or received no treatment, 11 were given oral rehydration solution either alone or in combination with intravenous fluid, 2 children oral intake was stopped

Limitations:
 *Serial interval, not incubation period

M/F-ratio: male-to-female ratio; NR: not reported; yrs: years

Author, journal, year, aim	Country, study design, study period and duration	Setting, source population , in/exclusion criteria, sample size, age, gender	Disease/Infectious agent, case definition, sampling, laboratory-methods
<p>Author: Mitchell</p> <p>Journal: J Pediatr</p> <p>Pub Year: 1993</p> <p>Aim: To evaluate astrovirus as a cause of diarrhea outbreaks among infants and toddlers in day care centers.</p>	<p>Country: United States</p> <p>Study design: Prospective surveillance study</p> <p>Study period & duration: January, 1986-March, 1987; December 1987-April 1988; January to March 1989; October 1989-December 1991</p>	<p>Setting: Day care centers</p> <p>Source population: Children <30 months who were enrolled in 17 DCCs, in Texas</p> <p>During each study period, children up to and including 24 months of age who were newly enrolled in the DCCs were enrolled in the study. Stool specimens were collected regardless of symptoms.</p> <p>Sample: *n=217 children tested, of whom n=73 children had laboratory-confirmed astrovirus infection, of whom n=35 were symptomatic (and n=38 were asymptomatic) *Age range: 6-30 months *Gender: NR</p>	<p>Disease/infectious agent: Astrovirus</p> <p>Case definition: *Diarrhea (passage of unformed stools with at least twice the usual daily frequency); and *Detection of astrovirus in a stool specimen</p> <p>Sampling (specimen, frequency, duration): *Stools *Collected weekly during study period *When diarrhea was identified, stools were collected twice weekly</p> <p>Lab Method: *Children with diarrhea had a stool tested for <i>Shigella</i>, <i>Salmonella</i>, <i>Campylobacter jejuni</i>, <i>Aeromonas</i>, <i>Yersinia enterocolitica</i>, <i>Plesiomonas</i>, and <i>Escherichia coli</i> O157:H7 by standard laboratory microbiologic procedures. *Enzyme immunoassay methods were used to detect enteric adenovirus types 40 and 41, group A rotavirus and Giardia lamblia antigens. *Astrovirus testing used the astrovirus biotin-avidin EIA and confirmed by RT-PCR.</p>
Outcome definition, results			Comments, limitations
<p>Outcome definition: Duration of shedding: Total duration (i.e. including time before onset of symptoms) astrovirus was found in stools</p> <p>Results: *Among children with a symptomatic infection: mean duration of total excretion (i.e. including time before onset of symptoms): range: 2-30 days; median 8.5 days *13 children were excreting astrovirus before diarrhea occurred (range: 1-8 days; median: 2 days) *9 children excreted astrovirus after diarrhea had ceased (range: 1-20 days; median 2 days)</p>			<p>Comments: *35 cases had diarrhea, 38 cases were asymptomatic *The total duration of excretion among asymptomatic children was 2-21 days (median 4 days) *Overall the total duration astrovirus was detected in stool specimens was: range: 11 to 44 days; median: 22 days</p> <p>Limitations: *Duration of shedding not given by number of days since onset of symptoms</p>
DCC: Day care centres; EIA: enzyme immunoassay; NR: not reported; RT-PCR: reverse transcriptase-polymerase chain reaction			

Gastroenteritis by norovirus/ calicivirus (n=14)

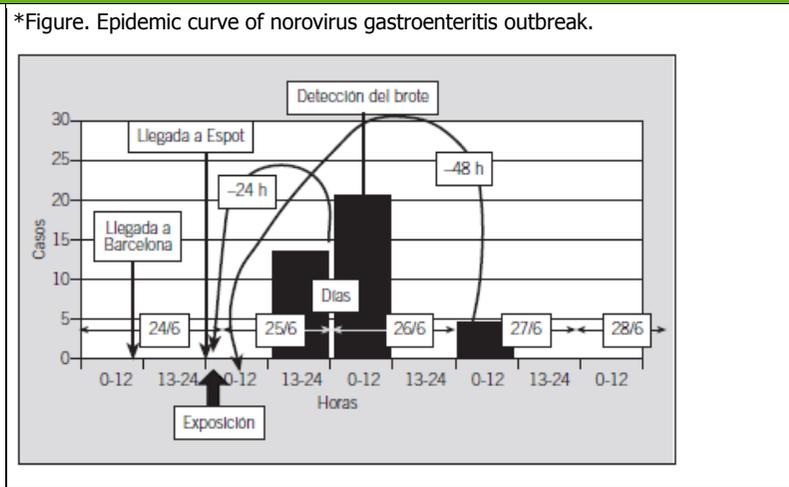

Author, journal, year, aim	Country, study design, study period and duration	Setting, source population, in/exclusion criteria, sample size, age, gender	Disease/Infectious agent, case definition, sampling, laboratory-methods
<p>Author: Barrabeig</p> <p>Journal: BMC Info Dis</p> <p>Pub Year: 2010</p> <p>Aim: To investigate the epidemiological characteristics of an outbreak of gastroenteritis due to norovirus that occurred in a residential summer camp in July 2005 and in which the involvement of a food handler was demonstrated.</p>	<p>Country: Spain</p> <p>Study design: Outbreak investigation</p> <p>Study period & duration: Exposure on 13 July 2005. Follow-up till 17 July 2005</p>	<p>Setting: Summer camp</p> <p>Source population: Children attending the residential summer camp in Barcelona</p> <p>Inclusion criteria: *Acute gastroenteritis within study period *Exposed to the lunch on 13 July</p> <p>Sample: *n=85 people were exposed to the lunch, of whom n=44 were infected *Median age of infected: 11 yrs (range: 9-50 yrs; ~4 adults) *Gender of infected: 66% male</p>	<p>Disease/infectious agent: <i>Norovirus GGII.2</i></p> <p>Source: Probably beef, served during the lunch on 13 July at 14:00</p> <p>Case definition: *Exposed person who presented vomiting or diarrhea (three or more loose stools within 24 h); and *At least two of the following symptoms: nausea, abdominal pain or fever measured by thermometer ($\geq 37.8^{\circ}\text{C}$); or clinical symptoms and *Norovirus detected in stool sample</p> <p>Sampling (specimen, frequency, duration): *Stools *NA</p> <p>Lab method: RT-PCR</p>
Outcome definition, results			Comments, limitations
<p>Outcome definition: Incubation period: Hours from lunch at 13 July (14:00) until onset of symptoms</p> <p>Results: Incubation period till onset of symptoms Range: 24-44.5 hours; mean: 32 hours</p>	<p>*Figure. Distribution of patients with acute gastroenteritis according to data of onset of symptoms.</p> <p style="font-size: small;">*Incubation period: 10-50 hours</p>		<p>Comments: *Two cases were probably due to person-to-person transmission and not included in the incubation period. If the source of infection of the two last cases was the suspected food, the incubation period would be 78 and 83 hours, respectively</p> <p>Limitations: *Approximately 4 adults included in the calculation of the incubation period *Only 10 stool samples were analysed (9 infants) and in 6/10 stool samples, norovirus was detected *Pathogenic bacteria were not isolated and virus not detected in the two suspected food and the statistical analysis did not establish any food as the vehicle of infection</p>
<p>RT-PCR: reverse transcription polymerase chain reaction; yrs: years.</p>			

Author, journal, year, aim	Country, study design, study period and duration	Setting, source population, in/exclusion criteria, sample size, age, gender	Disease/Infectious agent, case definition, sampling, laboratory-methods
Author: Godoy Journal: Med Clin (Barc) Pub Year: 2005 Aim: To investigate an outbreak of food-borne disease at a hotel.	Country: Spain Study design: Outbreak investigation Study period & duration: Exposure on June 24, 2002, outbreak started June 26 2002, investigation up to June 28	Setting: Hotel Source population: Group of 59 students and teachers at a hotel in Barcelona, Spain Inclusion criteria: *Met case definition Sample: *n=38 cases among students and teachers *Age: 15 yrs: n=17; 16 yrs: n=18; >17 yrs: n=3 *61% male	Disease/infectious agent: Norovirus Source: Sandwiches served at the hotel Case definition: *Student or teacher that presented with vomiting and/or diarrhea between the June 25 and 27, 2002, and 2 or more of the following symptoms: abdominal pain, fever, nausea; or clinical symptoms and *Culture-proven norovirus infection Sampling (specimen, frequency, duration): *Stools Lab method: RT-PCR

Outcome definition, results	Comments, limitations
-----------------------------	-----------------------

Outcome definition:
 Incubation period: Time from exposure to start of presentation of symptoms

Results:
 Median: 25.0 hours (range: 19-51 hours)

Comments:
 *Article in Spanish
 *2 people excluded by author because uncertain if they met the case definition

Limitations:
 *Incubation data includes data for 3 adults

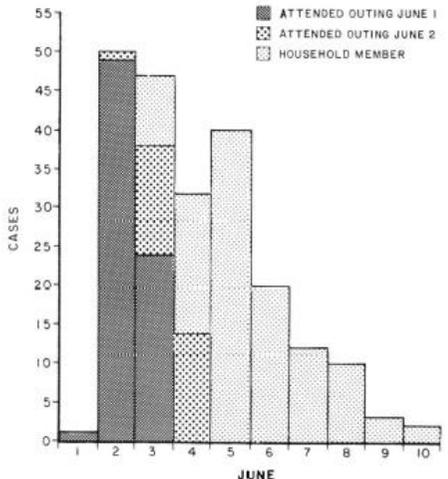

RT-PCR: reverse transcription polymerase chain reaction; yrs: years.

Author, journal, year, aim	Country, study design, study period and duration	Setting, source population , in/exclusion criteria, sample size, age, gender	Disease/Infectious agent, case definition, sampling, laboratory-methods
<p>Author: Grohmann</p> <p>Journal: J Clin Microbiol</p> <p>Pub Year: 1991</p> <p>Aim: To provide new information on the epidemiology of calicivirus infection.</p>	<p>Country: Australia</p> <p>Study design: Outbreak investigation</p> <p>Study period & duration: 12 January (one day after notification) until 15 March (Outbreak lasted 11 weeks), 1988</p>	<p>Setting: Day care center</p> <p>Source population: Children and staff members at a day care center, in Sydney</p> <p>Sample:</p> <ul style="list-style-type: none"> *Of the n=95 children and staff members, n=53 became ill during the outbreak, calicivirus positive stools for n=24 patients during an episode of gastroenteritis *Among the 24 calicivirus positive patients during an episode of gastroenteritis; children <60 months, n=19; adult staff, n=5 *Gender: NR 	<p>Disease/infectious agent: Calicivirus</p> <p>Source: NR, but the outbreak started in nursery</p> <p>Case definition:</p> <ul style="list-style-type: none"> *Human calicivirus gastroenteritis was defined as an episode of illness for which a fecal specimen collected 1 day before or within 7 days after the onset of symptoms was positive for HCV (and this was distinguished from asymptomatic cases and new onset cases) <p>Sampling (specimen, frequency, duration):</p> <ul style="list-style-type: none"> *Stool; 75 specimens from 53 ill persons in 8-day window (1 day before onset symptoms to 7 days after onset symptoms); the n=24 HCV-positive cases all had 1 sample within 8-day window *Additional 214 from 53 ill persons when they were well, outside of 8-day window <p>Lab Method: Fecal specimens were examined by microscopy and cultured. Paired sera were tested for antibody to the Norwalk virus by EIA, selected paired sera were also tested for antibody to calicivirus from the fecal specimens by IEM</p>

Outcome definition, results	Comments, limitations
<p>Outcome definition: Incubation period: NR Duration of shedding: duration of virus excretion in stool samples</p> <p>Results: Incubation period: Estimated by the authors to be 24-36 hours</p> <p>Duration of shedding: *HCV was excreted from at least 1 day before until >7 days after the onset of illness *Of the 24 calicivirus positive stools from patients with gastroenteritis collected within an 8-day window (ranging from 1 day before onset of symptoms to 7 days after onset of symptoms), 6 were collected on the day before the onset of symptoms, 5 on the day of onset, 10 from days 2-6 after onset of symptoms, and 3 on day 7. (NB: this information is based on one sample per person). Prolonged excretion (>7 days) was found in 2 children. (NR how many were tested)</p> <p>Exclusion period: *Exclusion: Until 24 hours after last episode of gastroenteritis. *Closure: 11 days</p> <p>One of the control measures was quarantine by temporarily excluding ill children and staff members from the center until 24 hours after their last episode of gastroenteritis; additionally the nursery was closed from January 14-25.</p> <p>Other control measures were: control of person-to-person spread (including improved hygiene, isolation of children who were ill from those who were well) and prevention of foodborne contamination by closing the kitchen and arranging for meals to be brought from home.</p> <p>Results: Closure and exclusion not effective. The outbreak subsided after 11 weeks, apparently independently of all the public health measures that had been taken.</p>	<p>Comments: *Diarrhea was the most common symptom in 57% of the patients, followed by vomiting (31%), nausea (23%), abdominal cramps (8%), and fever (5%), and many patients had more than one symptom</p> <p>Limitations: *The 24 positive stools included 5 from adult staff *Only one sample per person during the 8-day window *The method and population for estimating the incubation period was not reported (e.g. based on only calicivirus positive patients, or all patients with gastroenteritis, or all patients with gastroenteritis except if another pathogen was isolated)</p>
<p>EIA: enzyme immunoassay; HCV: human calicivirus; NR: not reported</p>

<p>Author: Davidson</p> <p>Journal: Lancet</p> <p>Pub Year: 1975</p> <p>Aim: To describe a survey of the etiology of sporadic acute enteritis in children in Melbourne during 12 months from November 1, 1973.</p>	<p>Country: Australia</p> <p>Study design: Case series</p> <p>Study period & duration: 12 months, starting November 1, 1973</p>	<p>Setting: Hospital</p> <p>Source population: Children admitted to Royal Children's Hospital, Melbourne</p> <p>Inclusion criteria: *Admitted with acute enteritis *For incubation period: acquired infection in hospital *For duration of shedding: remained in hospital for some time ("later specimens were collected from some patients with enteritis while they remained in hospital")</p> <p>Sample: *For incubation period: 116 hospitalized children in the 'control group' (without acute enteritis and no duovirus infection in specimens of feces obtained within 24 hours of admission to hospital); n=25 children developed symptoms of acute enteritis whilst in hospital; n=22 showed duovirus particles in stool extracts *Age range: 10 days to 12.5 yrs *M/F-ratio: 209/169</p> <p>*For duration of shedding: n=378 children with acute enteritis; n=197 with duovirus infection; n=16 were followed during their stay in hospital *Age range: 10 days to 6 yrs *M/F-ratio: 68/47</p>	<p>Disease/infectious agent: Rotavirus</p> <p>Source: NR, but probably infected children in hospital</p> <p>Case definition: *Acute enteritis: febrile illness <10 day's duration, associated with diarrhoea, with or without vomiting; and *Duovirus particles in stool extracts</p> <p>Sampling (specimen, frequency, duration): For incubation period: *Stools *NA For duration of shedding: *<24 after admission, and regularly during hospital stay, until negative sample</p> <p>Lab Method: Culture and standard isolation techniques; EM</p>

Outcome definition, results		Comments, limitations
<p>Outcome definition: Incubation period: Based on time from hospital admission to onset of acute enteritis Duration of shedding: Time from onset of symptoms to last positive sample before negative stool sample (definition by Pallas)</p> <p>Results: Incubation period: <48 hours Duration of shedding: *Range: 2 to 8 days from hospital admission *Median: 6 days from hospital admission (Number read from figure by Pallas)</p>	<p>*Figure. Duration and degree of duovirus excretion in feces from 16 children with acute enteritis</p>	 <p>Comments: *Duovirus = rotavirus</p> <p>Limitations: *For incubation period: study in hospitalized children</p>
<p>EM: electron microscopy; M/F-ratio: male-to-female ratio; yrs: years</p>		

Author, journal, year, aim	Country, study design, study period and duration	Setting, source population , in/exclusion criteria, sample size, age, gender	Disease/Infectious agent, case definition, sampling, laboratory-methods
<p>Author: Gaggero</p> <p>Journal: J Clin Microbiol</p> <p>Pub Year: 1992</p> <p>Aim: Using electropherotyping of RV as a means of comparing the genomes of clinical isolates to trace nosocomial RV transmission in a pediatric ward designated for diarrheal diseases in Santiago, Chile.</p>	<p>Country: Chile</p> <p>Study design: Case series</p> <p>Study period & duration: July 1985 to July 1987</p>	<p>Setting: Hospital</p> <p>Source population: Infants and children hospitalized in the ward at the Roberto del Río Children's Hospital, Santiago</p> <p>Inclusion criteria: *Hospitalized for acute diarrhea * <2 yrs of age</p> <p>Sample: *n=315 children identified with RV; data is available for n=11 patients from the study room during 1 month *Age of all cases: 0-2 yrs *Gender: NR</p>	<p>Disease/infectious agent: Rotavirus</p> <p>Case definition: *Acute diarrhea; and *RV detected in stool</p> <p>Sampling (specimen, frequency, duration): *Stools *Every other day during entire hospital stay. Daily sampling when positive case *Monitored until three consecutive specimens gave negative results</p> <p>Lab method: RNA electrophoresis screening</p>

Outcome definition, results **Comments, limitations**

Outcome definition:
 Duration of shedding: From detection in stool (upon admission or nosocomially acquired) until three consecutive negative specimens

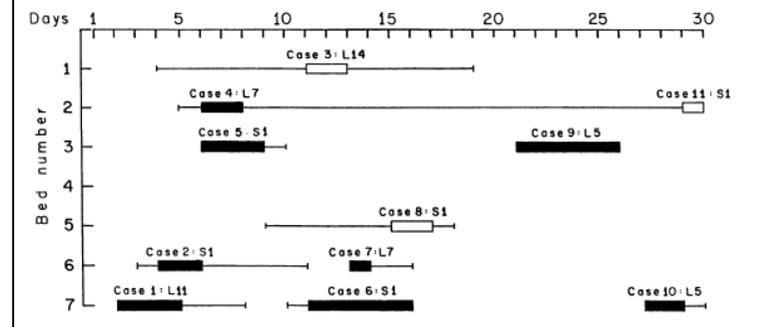

Results:
 Range: 1-5 days; mean: 2.5 days (Calculated by Pallas)

*Table. Number of days from detection in stool until 3 consecutive negative specimens, by individual case

Individual results	Number of days
Case 1	2
Case 2	2
Case 3	1
Case 4	3
Case 5	5
Case 6	2
Case 7	2
Case 8	1
Case 9	3
Case 10	5
Case 11	2

(Number of days read from figure by Pallas)

Figure: Temporal distribution of positive RV cases and their electropherotypes (shown in Fig. 1), isolated from patients admitted to one study room with seven beds during 1 month. Each line corresponds to the total hospitalisation period of a single positive case. Black and white blocks represent the RV shedding period of community- and hospital-acquired infections, respectively. The case number and corresponding electropherotype are specified over the blocks. The bed occupancy rate was over 85%, but cases without RV detection are not included in the figure.

Comments:
 NR

Limitations:
 *8/11 cases were diagnosed upon admission, 3/11 patients are hospital-acquired infections (RV shed beyond the third day after admission). For the eight cases diagnosed upon admission, duration of diarrhea before admission to the hospital was unknown
 *Start of measurement of duration of shedding was not at time of onset for all cases

NR: not reported; RNA: ribonucleic acid; RV: rotavirus; Yrs: years.

Exclusion or isolation of children for a defined period of time after illness is not practical, and identification of children before development of symptoms is impossible. In addition, many other children in the DCC setting may have periods of asymptomatic excretion. Asymptomatic shedding of rotavirus before and after a diarrhea episode, as identified in this study, represents a source of transmission that could best be avoided by appropriate handwashing procedures and diaper disposal after diaper changing.</p> <p>Limitations: *Duration of shedding not reported from time of onset of diarrhea *NR for how long diarrhea lasted</p>

<p>Author: Brodribb</p> <p>Journal: Lancet</p> <p>Pub Year: 1952</p> <p>Aim: To describe an outbreak of infective hepatitis in a boarding-school.</p>	<p>Country: United Kingdom</p> <p>Study design: Outbreak investigation</p> <p>Study period & duration: October 1950 to January 1951</p>	<p>Setting: Preparatory school</p> <p>Source population: Staff and pupils at a boys' preparatory school</p> <p>Inclusion criteria: *Part of the school's closed community (boys, adult teaching and nursing staff, adult domestic staff) *Developed symptoms definitely or strongly suggestive of hepatitis</p> <p>Sample: *n=90 people at the school; of whom n=50 developed symptoms definitely or strongly suggestive of hepatitis; of whom n=28 were likely infected by case 1, including two adults *Age among the 50 cases: boys aged 6-15 yrs, n=44; adults aged 19-40 yrs, n=6 *Gender: all children were boys; adults NR</p>	<p>Disease/infectious agent: Hepatitis A</p> <p>Case definition: *Symptoms definitely or strongly suggestive of hepatitis, i.e. jaundice, liver enlarged, pale stools (nearly every case started with one or more of the following: nausea, vomiting, severe anorexia, pain behind the eyes, giddiness, slight fever, or merely a typical slightly greyish pallor)</p> <p>Sampling (specimen, frequency, duration): *NA</p> <p>Lab Method: NA</p>
Outcome definition, results			Comments, limitations
<p>Outcome definition: Serial interval: The interval between onset in case 1 and onset in the first waves of secondary cases (based on onset of early symptoms; not necessarily jaundice)</p> <p>Results: Serial interval: *Range: 20-32 days *Median: 27 days</p>			<p>Comments: NR</p> <p>Limitations: *Serial interval, not incubation period</p>
<p>NA: not applicable; NR: not reported; yrs: years</p>			

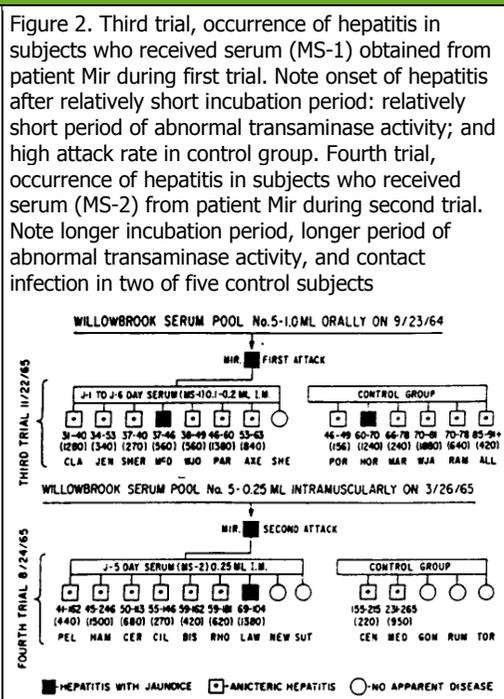

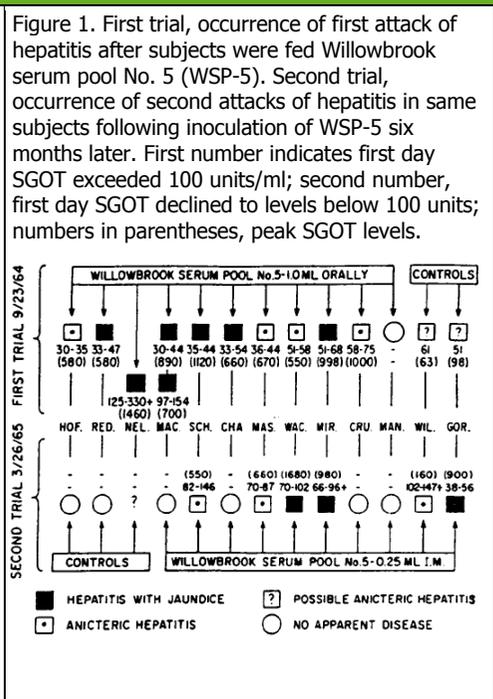

Author, journal, year, aim	Country, study design, study period and duration	Setting, source population, in/exclusion criteria, sample size, age, gender	Disease/Infectious agent, case definition, sampling, laboratory-methods
Author: Krugman Journal: JAMA Pub Year: 1967 Aim: To provide evidence for the presence of two distinctive clinical, epidemiological and immunological types of infectious hepatitis.	Country: United States Study design: Series of 7 non-randomized clinical trials with comparison between experimental induced hepatitis and controls (1st and 3rd were about hepatitis A, others about hepatitis B) Study period & duration: September 1964 to January 1967	Setting: Institutional school Source population: Children attending Willowbrook State School for retarded children, New York, Staten Island Inclusion criteria: *Newly admitted children Sample: *Trial 1: n=11 children fed blood serum infected with hepatitis A, of whom n=10 became symptomatic; Trial 3: n=8 children were administered blood serum infected with hepatitis A; of whom n=7 became symptomatic *Age range: 3-10 yrs *Gender: NR	Disease/infectious agent: Hepatitis A Source: Virus isolated from blood serum of other patients Case definition: *Hepatitis with jaundice: the occurrence of clinical jaundice associated with an abnormal serum bilirubin and an abnormal serum glutamic oxalacetic transaminase (SGOT); Hepatitis without jaundice: the serum bilirubin value was less than 1.0 mg/100 ml but in which a crescendo-like rise in SGOT activity exceeded 100 units. Sampling (specimen, frequency, duration): *Blood *At weekly intervals or more often Lab Method: Serum bilirubin, thymol turbidity, SGOT and bilirubin in the urine

Outcome definition, results	Comments, limitations
-----------------------------	-----------------------

Outcome definition:
 Incubation period: Defined as the number of days between exposure and first evidence of abnormal serum transaminase activity as indicated by a SGOT level above 100 units. Data extracted for symptomatic children (i.e. those with (possible) anicteric hepatitis or hepatitis with jaundice) from two trials (trials 1 & 3). Data pooled to obtain median

Results:
 *Median: 37 days
 *Range: 30-125 days

(Number extracted from figures by Pallas)

Comments:
 *The children have low capability to maintain hygiene; this influences transmission
 *The children were admitted directly to a special isolation facility capable of housing up to 16 children.
 *The 10 cases in the first trial were induced by oral administration of Willowbrook serum pool; the 7 cases in the third trial were induced by giving MS-1 serum intramuscularly

Limitations:
 *Definition of incubation period based on a laboratory-value, not a clinical symptom (although all cases presented here are symptomatic). The authors remark that definitions vary between studies; and most often incubation period has been measured as the number of days between exposure and either onset of symptoms or onset of jaundice; however jaundice may occur 2 days before or 2 weeks after illness onset and at Willowbrook most cases were anicteric and asymptomatic
 *Incubation period includes children who are asymptomatic

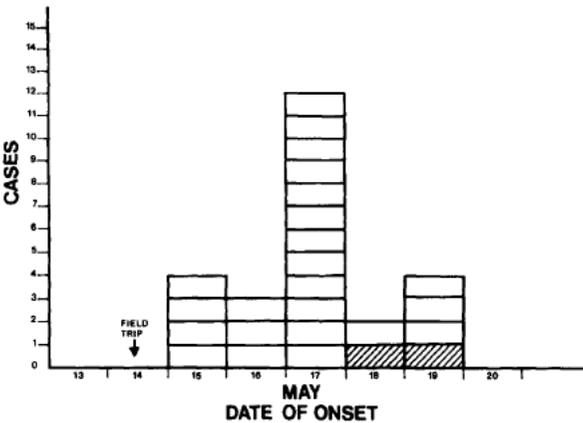

NR: not reported; SGOT: serum glutamic oxalacetic transaminase; yrs: years

Author, journal, year, aim	Country, study design, study period and duration	Setting, source population, in/exclusion criteria, sample size, age, gender	Disease/Infectious agent, case definition, sampling, laboratory-methods
<p>Author: Reid</p> <p>Journal: Public Health</p> <p>Pub Year: 1986</p> <p>Aim: To investigate outbreaks of hepatitis A in two primary schools in different parts of a city.</p>	<p>Country: United Kingdom</p> <p>Study design: Outbreak investigation</p> <p>Study period & duration: Outbreak in school 1 started December 1983; outbreak in school 2 started in October 1983</p>	<p>Setting: Schools</p> <p>Source population: Children attending one of 2 mixed junior and infants school in Liverpool</p> <p>Sample:</p> <p>School 1: *n=121 children (93 in main school, 28 in nursery); cases identified by questionnaire (response rate ~95%); n=28 cases *In the main school: 46 boys (19 cases) and 47 girls (9 cases)</p> <p>School 2: *n=371; cases identified by questionnaires (response rate 166/76 (94%), 129/135 (96%) and 52/60 (86%) in junior department, infants pupil department and among voluntary pupils, respectively); n=16 cases *92 boys (9 cases), 84 girls (4 cases)</p>	<p>Disease/infectious agent: Hepatitis A virus</p> <p>Case definition: *Child with a definite history of jaundice. This information was obtained by asking the parents on the questionnaire "Has your child ever had (yellow) jaundice or hepatitis?" Confirmation of affirmative answers was sought from notifications, sickness absence notes, teachers and, in a few cases, examination of blood samples.</p> <p>Lab method: Serum samples tested for IgM antibody to hepatitis A; technique NR</p>
Outcome definition, results			Comments, limitations
<p>Exclusion period: Until clinical recovery.</p> <p>The following control measures were instigated in both schools:</p> <ol style="list-style-type: none"> 1. Daily visits to advise teachers about exclusion from school of children ""whose health caused them concern""; to keep a daily diary of absent children with reasons for absence; to check children returning to school after absence to ensure they had clinically recovered. 2. Standard regime for disinfecting toilets 3x/day with hypochlorite solution 3. Teachers repeatedly encouraged children to wash their hands (after toilet use, before meals) 4. In school 1, normal human immunoglobulin given on 28th November 1983 to all regular attenders at nursery class (no cases had occurred there, it was felt spread would probably be rapid among such young children if a case did occur) and offered to staff <p>Results:</p> <p>These measures were apparently successful because no further cases occurred in either school after the lapse of one incubation period from the date the measures were instituted.</p>			<p>Comments:</p> <p>NR</p> <p>Limitations:</p> <p>*Multiple control measures instituted at once, therefore impossible to distil the role of exclusion</p>
IgM: immunoglobulin M; NR: not reported.			

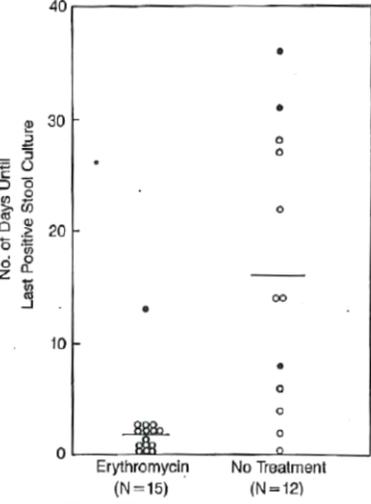

Bacterial infections

Campylobacteriosis (n=8)

Author, journal, year, aim	Country, study design, study period and duration	Setting, source population, in/exclusion criteria, sample size, age, gender	Disease/Infectious agent, case definition, sampling, laboratory-methods								
<p>Author: Evans</p> <p>Journal: Epidemiol Infect</p> <p>Pub Year: 1996</p> <p>Aim: To describe an outbreak of <i>Campylobacter</i> which occurred among nursery school children following an educational visit to a dairy farm.</p>	<p>Country: United Kingdom</p> <p>Study design: Outbreak investigation</p> <p>Study period & duration: Exposure on 28 March 1994; questionnaire sent in April</p>	<p>Setting: Working dairy farm</p> <p>Source population: Nursery school class (including children, staff and parent helpers) that visit a nearby working dairy farm, in/around Cardiff</p> <p>Inclusion criteria: *Gastrointestinal infection *Visited farm</p> <p>Sample: *n=23 cases (20 children and 3 adults) *Age of children: 3-4 yrs; adults *Gender: NR</p>	<p>Disease/infectious agent: <i>Campylobacter jejuni</i></p> <p>Source: Raw cow milk at dairy farm</p> <p>Case definition: *Diarrhea or abdominal pain within 10 days of the farm visit; and/or *Culture-confirmed <i>Campylobacter</i> infection.</p> <p>Sampling (specimen, frequency, duration): *Stools *NA</p> <p>Lab Method: Culture</p>

<p>HUS: hemolytic-uremic syndrome; NR: not reported</p>																																																																																																																															

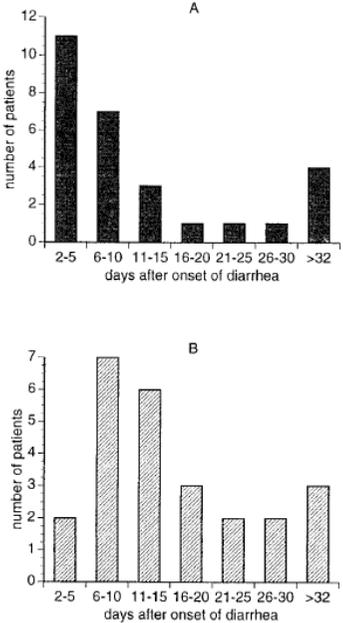

Author, journal, year, aim	Country, study design, study period and duration	Setting, source population, in/exclusion criteria, sample size, age, gender	Disease/Infectious agent, case definition, sampling, laboratory-methods
<p>Author: Brandt</p> <p>Journal: J Pediatrics</p> <p>Pub Year: 1994</p> <p>Aim: To describe the clinical course of the patients, compare the experience with previously reported outbreaks of HUS (hemolytic-uremic syndrome), and to discuss the public health implications of epidemic <i>E. coli</i> O157:H7-associated HUS.</p>	<p>Country: United States</p> <p>Study design: Case series</p> <p>Study period & duration: December 1, 1992 to February 28, 1993</p>	<p>Setting: Hospital and medical center</p> <p>Source population: Children seen at the children's hospital and medical center in Seattle</p> <p>Inclusion criteria: *Characteristic features of HUS (microangiopathic hemolytic anemia, thrombocytopenia, and azotemia) *Onset of a gastrointestinal prodrome within the 21 days before HUS developed *Ingestion of all or a part of a hamburger at an establishment known to have received <i>E. coli</i> O157:H7-tainted ground beef and implicated in the outbreak through evaluations by the Washington State Department of Health or; *Close contact with an individual with culture-confirmed <i>E. coli</i> O157:H7 enterocolitis or; *Isolation of <i>E. coli</i> O157:H7 in culture of a stool sample</p> <p>Exclusion criteria: *History of proteinuria before HUS</p> <p>Sample: *n=37 children who met the case definition were identified of whom n=26 had a known exposure date *Median age of all cases: 5 yrs (range: 1-15 yrs) *Gender of all cases: 43% male</p>	<p>Disease/infectious agent: <i>E. coli</i> O157:H7</p> <p>Source: Hamburger made of <i>E. coli</i> O157:H7-tainted ground beef</p> <p>Case definition: *Gastrointestinal symptoms (hemorrhagic colitis, rectal prolapse, vomiting and abdominal pain without diarrhea); and *<i>E. coli</i> O157H7 confirmed by culture of a stool sample</p> <p>Sampling (specimen, frequency, duration): *Stools</p> <p>Lab method: MacConkey-sorbitol agar and O157 particle agglutination test</p>
Outcome definition, results			Comments, limitations
<p>Outcome definition: Incubation period: Days from exposure to onset of gastrointestinal symptoms</p> <p>Results: Days until onset of symptoms Range: <1 day to 21 days; median: 4.5 days</p>			<p>Comments: *32/37 children had <i>E. coli</i> confirmed by culture of a stool sample</p> <p>Limitations: *Sample comprised children who develop HUS after <i>E. coli</i> O157:H7. This group could differ from children who do not develop HUS</p>
<p>HUS: hemolytic-uremic syndrome; yrs: years.</p>			

Author, journal, year, aim	Country, study design, study period and duration	Setting, source population , in/exclusion criteria, sample size, age, gender	Disease/Infectious agent, case definition, sampling, laboratory-methods
<p>Author: Brown</p> <p>Journal: <i>Pediatr Infect Dis J</i></p> <p>Pub Year: 2012</p> <p>Aim: To investigate an outbreak of O26:H11 infection among children <48 months of age and employees at a child care center; to determine the cause and extent of the outbreak and to prevent and control further illness among children and employees at the center.</p>	<p>Country: United States</p> <p>Study design: Outbreak investigation</p> <p>Study period & duration: May 24 to August 27, 2010</p>	<p>Setting: Child care center</p> <p>Source population: Employees and children in childcare center (with 3 infant rooms (age 6 weeks-18 months), 2 toddler rooms (18-35 months) and a 3-year-old room (36-47 months)), in Colorado</p> <p>A questionnaire was sent to all employees and parents of every child <48 months. Both confirmed and suspected cases were included, but shedding duration was only presented for confirmed symptomatic cases for whom follow-up testing was available</p> <p>Sample: *n=55 children, of whom n=33 were cases; of whom n=17 were confirmed (and n=16 suspected); following up testing available for 12/13 confirmed symptomatic cases. *Age among confirmed cases <12 months, n=6; 12-23 months, n=4; 24-35 months, n=2; 36-47 months, n=5 *Gender: NR</p>	<p>Disease/infectious agent: <i>E. coli</i> O26:H11</p> <p>Case definition: *Confirmed case: Laboratory confirmed O26:H11 *Suspected case: Any diarrheal illness beginning on or after May 24, 2010</p> <p>Sampling (specimen, frequency, duration): *Stool *Frequencies and intervals of follow-up testing were based on convenience and were therefore variable for each patient</p> <p>Lab Method: Isolates were tested using standard STEC biochemical panel and shiga toxin PCR, and then forwarded to CDC for serotyping. Isolated were characterized by pulsed-field gel electrophoresis</p>
Outcome definition, results			Comments, limitations
<p>Outcome definition: Duration of shedding in symptomatic confirmed cases: Interval between the onset of illness and the date of the first negative Shiga toxin PCR test</p> <p>Results: *Range: 14-52 days after onset of illness *Median: 30.5 days after onset of illness *Duration of shedding was ≥ 3 weeks for 10 (83%) children *Intermittent shedding (one or more positive tests after the first negative test was obtained in a patient) was detected in 3 (17%) confirmed cases. Among these, the maximum intervals between positive specimens were 8, 14, and 31 days.</p>			<p>Comments: *4 (22%) confirmed cases were asymptomatic, including one employee. As only one employee was confirmed, all other confirmed cases were children</p> <p>Limitations: *Calculation of the duration of shedding is likely to be an overestimate because children who shed for shorter periods were more likely to be negative when they were first tested</p>
<p>CDC: Center for Disease Control and Prevention; NR: not reported; PCR: polymerase chain reaction; STEC: shiga-toxin producing <i>E. coli</i></p>			

Author, journal, year, aim	Country, study design, study period and duration	Setting, source population , in/exclusion criteria, sample size, age, gender	Disease/Infectious agent, case definition, sampling, laboratory-methods
<p>Author: Dabke</p> <p>Journal: Epidemiol Infect</p> <p>Pub Year: 2013</p> <p>Aim: To assess the duration of shedding and estimate the risk of transmission of VTEC from infectious young children in child care facilities in England and to help inform any revision of national guidance.</p>	<p>Country: United Kingdom</p> <p>Study design: Case series</p> <p>Study period & duration: 18 months (2010-2011)</p>	<p>Setting: Childcare facilities (schools and nurseries)</p> <p>Source population: National enhanced VTEC surveillance system</p> <p>Inclusion criteria:</p> <ul style="list-style-type: none"> *Laboratory confirmed VTEC cases aged ≤5 years *Residing in England *Attending childcare facilities including schools and nurseries *Disease onset between January 1, 2010 and July 7, 2011 *Data was available on HPZone <p>Sample:</p> <ul style="list-style-type: none"> *n=349 confirmed VTEC cases aged ≤5 yrs in HPZone; of which n=234 attended childcare facilities; for whom n=225 information was available in HPZone and were included in the study. 204 cases were symptomatic. Duration of shedding calculated for 151/225; duration of exclusion for n=162/225. *Age range among children included in the study: 0-71 months; median 3 yrs (IQR 2-4) *M/F-ratio among children included in the study: 107/118 	<p>Disease/infectious agent: VTEC: <i>E. coli</i> O157 (98.7%), <i>E. coli</i> O26 (1.3%), missing (0.9%); PT21/28 (37%), PT8 (30%), PT2 (10%)</p> <p>Case definition:</p> <ul style="list-style-type: none"> *An individual with VTEC isolation confirmed by PCR identification of verocytotoxin-encoding genes by the reference laboratory (Laboratory of Gastrointestinal Pathogens at HPA Colindale, London). *Primary, co-primary, secondary case definition according to HPA guidance <p>Sampling (specimen, frequency, duration):</p> <ul style="list-style-type: none"> *Stool *NR <p>Lab Method: PCR identification of verocytotoxin-encoding genes by the reference laboratory (Laboratory of Gastrointestinal Pathogens at HPA Colindale, London)</p>

Outcome definition, results		Comments, limitations																																				
<p>Outcome definition: Duration of shedding: Interval from date of onset of illness to the date of the first of two consecutive negative stool specimens.</p> <p>Results: *Median: 31 days after onset of illness (IQR 17-41 days) *48% (95%CI 40-56) shed ≤30 days; 44% (95%CI 36-52) shed for 31-60 days; 8% (95%CI 4-12) shed for >60 days *Younger children shed for longer (7% drop in duration of shedding per year, 95% CI 1-14, p=0.04); no significant difference by gender or phage type.</p> <p>Exclusion period defined as interval from date of onset to the date when the child was cleared to return to the childcare setting. <p>Author: Karch</p> <p>Journal: J Clin Microbiol</p> <p>Pub Year: 1995</p> <p>Aim: To investigate the length of time that Shiga-like toxin-producing <i>Escherichia coli</i> O157 is excreted after the onset of diarrhea/to determine the potential role of long-term carriage in infection spread among children not treated with antibiotics</p>	<p>Country: Germany</p> <p>Study design: Monitoring study</p> <p>Study period & duration: March 1988 to December 1993</p>	<p>Setting: Pediatric centers</p> <p>Source population: Children attending different pediatric centers in Germany</p> <p>Inclusion criteria: *Diarrhea or hemorrhagic colitis; or HUS *Had not received any antibiotic treatment</p> <p>Sample: *n=53 cases (diarrhea or hemorrhagic colitis: n=28, HUS n=25); n=456 serial stool samples obtained *Median age: 3.6 yrs; range 7 months to 9 yrs *Gender: NR</p>	<p>Disease/infectious agent: <i>E. coli</i> O157</p> <p>Case definition: *Diarrhea or hemorrhagic colitis; or HUS; and *Confirmed <i>E. coli</i> O157</p> <p>Sampling (specimen, frequency, duration): *Stool samples *2-4 day intervals</p> <p>Lab Method: DNA probes followed by agglutination with a specific antiserum.</p>																																	
Outcome definition, results			Comments, limitations																																	
<p>Outcome definition: Duration of shedding: Interval from onset of diarrhea to the last positive sample followed by three negative stool cultures.</p> <p>Results: *Diarrhea or hemorrhagic colitis patients: Range: 2-62 days after onset of diarrhea Mean or median: 13 days after onset of diarrhea *HUS patients: Range: 5-124 days after onset of diarrhea Mean or median: 21 days after onset of diarrhea *Shedding significantly longer in patients with HUS than in those with only diarrhea or hemorrhagic colitis (p<0.001) *In 36 patients (68%) only the first culture was O157 positive and the 3 cultures that followed were negative *12 patients (incl. 7 with HUS) were intermittent shedders</p>		<p>*Figure. Recovery of <i>E. coli</i> O157 in stool samples from patients with diarrhea (A) and HUS (B). The duration of shedding was estimated as the interval from onset of diarrhea to the last O157-positive culture followed by 3 negative stool cultures collected at 2-4 day intervals.</p>	 <p>Figure A: Recovery of <i>E. coli</i> O157 in stool samples from patients with diarrhea. The x-axis represents days after onset of diarrhea (2-5, 6-10, 11-15, 16-20, 21-25, 26-30, >32). The y-axis represents the number of patients (0 to 12). The distribution is as follows:</p> <table border="1"> <thead> <tr> <th>Days after onset of diarrhea</th> <th>Number of patients</th> </tr> </thead> <tbody> <tr> <td>2-5</td> <td>11</td> </tr> <tr> <td>6-10</td> <td>7</td> </tr> <tr> <td>11-15</td> <td>3</td> </tr> <tr> <td>16-20</td> <td>1</td> </tr> <tr> <td>21-25</td> <td>1</td> </tr> <tr> <td>26-30</td> <td>1</td> </tr> <tr> <td>>32</td> <td>4</td> </tr> </tbody> </table> <p>Figure B: Recovery of <i>E. coli</i> O157 in stool samples from patients with HUS. The x-axis represents days after onset of diarrhea (2-5, 6-10, 11-15, 16-20, 21-25, 26-30, >32). The y-axis represents the number of patients (0 to 7). The distribution is as follows:</p> <table border="1"> <thead> <tr> <th>Days after onset of diarrhea</th> <th>Number of patients</th> </tr> </thead> <tbody> <tr> <td>2-5</td> <td>2</td> </tr> <tr> <td>6-10</td> <td>7</td> </tr> <tr> <td>11-15</td> <td>6</td> </tr> <tr> <td>16-20</td> <td>3</td> </tr> <tr> <td>21-25</td> <td>2</td> </tr> <tr> <td>26-30</td> <td>2</td> </tr> <tr> <td>>32</td> <td>3</td> </tr> </tbody> </table>	Days after onset of diarrhea	Number of patients	2-5	11	6-10	7	11-15	3	16-20	1	21-25	1	26-30	1	>32	4	Days after onset of diarrhea	Number of patients	2-5	2	6-10	7	11-15	6	16-20	3	21-25	2	26-30	2	>32	3	<p>Comments: *For the patients with diarrhea or hemorrhagic colitis only, the first stool samples were collected 1-6 days after onset of diarrhea (median 3 days). For the patients with HUS, stools were collected during the acute phases of HUS (range 7-17 days after onset of diarrhea; median 9 days) *Comparison of the first and <i>last E. coli</i> O157 isolated by pulsed-field gel electrophoresis revealed that in 3/7 long-term shedders, pulsed-field gel electrophoresis types varied. In 2 cases, a Shiga-like toxin gene was apparently lost during infection.</p> <p>Limitations: *Unclear if the shedding duration is expressed as a mean or as a median, or whether the median and the mean as the same (in the abstract the authors wrote 'median', in the text they wrote 'mean')</p>

<p>Author: MacDonald</p> <p>Journal: BMC Info Dis</p> <p>Pub Year: 2014</p> <p>Aim: To describe the results of the outbreak investigation and discuss the implications of screening and the exclusion policies for children attending daycare in Norway.</p>	<p>Country: Norway</p> <p>Study design: Outbreak investigation</p> <p>Study period & duration: Study period from September 1 to October 31, 2012. October 16, 2012 the National institute of Public Health was notified, school was closed on 17 October for extensive cleaning and reopened on 22 October</p>	<p>Setting: Daycare centre</p> <p>Source population: Children at the daycare center, southern Norway</p> <p>Inclusion criteria: *Tested positive for <i>STEC</i> between September 1 and October 31, 2012 *Submitted a stool sample prior to returning to the daycare centre *Attending the daycare centre during study period</p> <p>Sample: *n=91 children attended daycare centre during study period, of whom n=9 tested positive for <i>E. coli</i> (6 confirmed cases, 3 probable cases), and n=6 had symptoms (5 confirmed cases, 1 probable case) *Median age of all positive cases: 2 yrs (range: 1-4 yrs) *Gender of all positive cases: 88.9% male</p>	<p>Disease/infectious agent: <i>E. coli</i> O103:H2, <i>eae</i> and <i>stx1a</i>-positive (n=5), <i>eae</i> and <i>stx1</i>-positive (n=1)</p> <p>Case definition: *Symptoms (fever or diarrhea); and *Only preliminary <i>stx</i>-gene finding in a stool sample (probable case) or <i>STEC</i> infection confirmed by the National Reference Laboratory (confirmed case)</p> <p>Sampling (specimen, frequency, duration): *Stools *Samples collected at minimum interval of 24 hours until 5 consecutive specimens were obtained *Samples collected till October 31, 2012</p> <p>Lab method: PCR-method</p>
Outcome definition, results			Comments, limitations
<p>Outcome definition: Duration of shedding: Period between symptom onset and the date of the first negative control test</p> <p>Results: Days of shedding from start of onset of symptoms Range: 7 - 98 days</p> <p>Exclusion period: *Total duration of exclusion for n=9 cases (6 symptomatic, 3 asymptomatic cases): 459 days. Median exclusion period: 53 days per child *Duration of exclusion for confirmed cases (n=6, including one asymptomatic case): range 37 - 109 days; median: 71 days</p> <p>School was closed on October 17, and reopened on October 22, 2012 for children who had negative test results for <i>STEC</i>. Duration of exclusion from daycare was calculated as the period of symptom onset (or date of testing for asymptomatic cases) to the date of the last required control test. The required number of consecutive negative control tests before returning to daycare was 5 consecutive negative results (diagnosed with <i>stx2</i>-positive <i>STEC</i> or a <i>STEC</i> serogroup; uncomplicated diarrhea with only <i>stx1</i>-positive <i>STEC</i> but serotype previously associated with HUS; or <i>STEC</i> infection with severe clinical presentation, such as bloody diarrhoea or HUS) or 3 consecutive negative results (uncomplicated diarrhea with only <i>stx1</i>-positive <i>STEC</i>).</p> <p>Results: The outbreak was interrupted</p>	<p>*Figure. Dates of symptom onset, first positive test and first negative test of confirmed and probable <i>E. coli</i> cases at the daycare</p> <p>X Week of onset of symptoms T Week of first positive test N Week of first negative test</p> <p>P: Probable case O103: Confirmed STEC O103 O91: Confirmed STEC O91 * Asymptomatic</p>	<p>Comments: *For children wearing diapers and the frequency of diarrhea, parents were asked to specify whether their child had looser stools than normal, more frequent stools than normal and/or diarrhea</p> <p>Limitations: *As a sensitive definition for possible cases of <i>STEC</i> infection was used, it is conceivable that cases of gastroenteritis of differing etiology, such as norovirus, occurred during the same period</p>

<p>EAEC: enteroaggregative <i>E. coli</i>; ELISA: enzyme-linked immunosorbent assay; ESBL: extended-spectrum β-lactamase; HUS: haemolytic uremic syndrome; STEC: Shiga toxin-producing <i>Escherichia coli</i></p>	<p>Comments: *The outbreak strain differs essentially from typical STEC strains because it displays a hybrid virulence profile that combines typical molecular and phenotypic characteristics of STEC and EAEC and phylogenetically belongs to EAEC rather than to STEC *The date of disease onset was known for 234 patients (72,9%) whereas for 87 patients (27.1%) no exact date for the onset of disease was available, to still include these patients, a median delay between onset of symptoms and hospitalisation was calculated (4 days) *77/321 was the last available pooled test results still positive, as a consequence, patients were right censored *Figure is available shedding duration by age group, however this includes patients who received antibiotics *Figure is available shedding duration by antibiotic yes/no, however this includes adults</p> <p>Limitations: *HUS patients are strongly overrepresented among cases in this study because more cases were selectively referred to the participating tertiary care hospitals *Because culture media selective for ESBL-carrying bacteria were used for the follow up cultures, there is a potential risk to underestimate shedding time if the strain lost the ESBL plasmid *A significant part of the hospitalized patients received antibiotic therapy this fact may lead to a slight overestimation of the shedding time in antibiotic treated patients *Patients age had influence on the duration of <i>E. coli</i> shedding *The type and the overall number of tests applied for the diagnosis of STEC infection differed between participating centres *The sensitivity and specificity of the particular tests used by the participating centres varies</p>																																	

Non-typhoid *Salmonella* infections (n=12)

Author, journal, year, aim	Country, study design, study period and duration	Setting, source population, in/exclusion criteria, sample size, age, gender	Disease/Infectious agent, case definition, sampling, laboratory-methods
<p>Author: Abe</p> <p>Journal: J Food Prot</p> <p>Pub Year: 2004</p> <p>Aim: To study the factors underlying the long incubation periods of several gastroenteritis outbreaks caused by <i>Salmonella</i>-contaminated lunches at elementary, junior high and nursery schools frequently observed between 1990 and 1999.</p>	<p>Country: Japan</p> <p>Study design: Multiple survey analysis</p> <p>Study period & duration: 1982 - 2002</p>	<p>Setting: Elementary and junior high schools; nursery schools; restaurants, take-out food shops and hotels; and hospital and welfare facilities</p> <p>Source population: "Food Poisoning Investigation Reports" collected from 39 prefectures and 9 government-designated major cities in Japan from 1982-2002 describing outbreaks caused by <i>Salmonella enteritidis</i> (SE) and had data for incubation periods and microbiological tests</p> <p>Inclusion criteria: *The number of patients in the outbreak was ≥ 10 *Fecal cultures were positive for <i>Salmonella enteritidis</i> negative for other pathogens *Causative meals or dishes were identified on the basis of microbiological tests or through interviews with the patients regarding foods eaten before the onset of disease</p> <p>Sample: *185 outbreaks with n=27,463 patients; 35 outbreaks were in elementary and junior high schools and 17 in nursery schools *Average age: 10.6 yrs in schools and 4.5 yrs in nursery schools. *M/F-ratio for all patients: 54.2%/45.8%</p>	<p>Disease/infectious agent: <i>Salmonella enteritidis</i></p> <p>Source: School and nursery school lunches</p> <p>Case definition: *NR</p> <p>Sampling (specimen, frequency, duration): *NR</p> <p>Lab Method: NR (only for the foods)</p>
Outcome definition, results		Comments, limitations	
<p>Outcome definition: In the investigation reports (surveys), each patient is tabulated in terms of incubation period (every 6 to 24 h). Authors selected the middle time of each incubation period range as the representative value, and the median incubation period was calculated from the representative value of the range.</p> <p>Results: *Elementary and junior high schools: median (\pm SD): 80.9 (\pm 35.876) hours *Nursery schools: median (\pm SD): 64.8 (\pm 21.583) hours</p>	<p>*Figure. Distribution of median incubation period of <i>Salmonella Enteritidis</i> outbreaks classified according to kind of causative cooking facilities: (A) elementary and junior high school lunches, 35 outbreaks; (B) nursery school lunches, 17 outbreaks</p> <div style="display: flex; justify-content: space-around;">  </div>		<p>Comments: *The distribution of incubation periods was broader for school and nursery school lunches than for the other groups (i.e. restaurant, take out food-shops, hotels, and hospital and welfare facilities). The median incubation period was significantly longer for school and nursery school lunches than for food prepared in other cooking facilities ($p < 0.01$), presumably because of the significantly shorter time elapsed from the start of the cooking process to the consumption of school and nursery school lunches, suggesting limited bacterial growth. NB, for the comparisons: Outbreaks other those in schools and nurseries likely include many adults *A significant negative correlation between the bacterial dose ingested per person and the median incubation period was shown (over all cooking facilities, $p < 0.01$) *A negative correlation was observed between the attack rate and the median incubation period (analysis of 50 food poisoning cases caused by school and nursery school lunches)</p> <p>Limitations: *NR how many cases were involved in the school and nursery outbreaks *It is possible that the outbreaks at schools and nurseries still include a few adults (e.g. teachers, kitchen staff)</p>

Author, journal, year, aim	Country, study design, study period and duration	Setting, source population , in/exclusion criteria, sample size, age, gender	Disease/Infectious agent, case definition, sampling, laboratory-methods
<p>Author: Cowden Journal: Epidemiol Infect Pub Year: 1989</p> <p>Aim: To investigate a sudden increase in the number of reports received by CDSC of <i>S. Typhimurium</i> DT 124 infections and identify the source of infection.</p>	<p>Country: United Kingdom</p> <p>Study design: Outbreak investigation</p> <p>Study period & duration: December 1987 to February 1988</p>	<p>Setting: Countrywide</p> <p>Source population: Surveillance of laboratory reports from medical microbiology laboratories of the NHS and PHLS</p> <p>Inclusion criteria: *<i>S. Typhimurium</i> DT infection as reported in weekly laboratory surveillance scheme *Primary cases</p> <p>Sample: *n=101 confirmed isolated; n=85 cases were interviewed; of these 72 were primary cases; incubation period was based on n=59 primary cases for whom dates of consumption and disease onset were known (16/85 were prescribed antibiotics) *Among the 85 cases, age range: 7 months-78 yrs; median age: 6 yrs; most were children *M/F-ratio: 46/39</p>	<p>Disease/infectious agent: <i>Salmonella</i> Typhimurium DT 124</p> <p>Source: Salami sticks</p> <p>Case definition: *Primary cases: Persons who had had diarrhoea, the epidemic phage type isolated from their stools, and no other member of the family had previously had diarrhoea since 1 Dec, 1987.</p> <p>Sampling (specimen, frequency, duration): *Stools *NA</p> <p>Lab Method: Incubation and screening of colonies giving the appearance of <i>Salmonella</i> by testing with polyvalent and 04 <i>Salmonella antisera</i> and those giving a positive reaction were sent to Division of Enteric Pathogens for phage typing.</p>
Outcome definition, results			Comments, limitations
<p>Outcome definition: Incubation period: Time between the date of consumption of salami sticks and onset of symptoms</p> <p>Results: *Median: 1-3 days *<24 hours: n=5; 1-3 days: n=41; 4-7 days: n=11; >7 days: n=2</p>			<p>Comments: *Out of 72 primary cases, 68 had eaten a same type of salami stick. *81/85 reported diarrhoea, 35 reported blood in their stools, 38 reported vomiting and 71 fever; 2 cases developed complications. *First <i>Salmonella</i> outbreak with fermented meat product in the United Kingdom</p> <p>Limitations: * 22/85 were prescribed medication. Of these, 16 were prescribed antibiotics</p>
<p>M/F-ratio: male-to-female ratio; NA: not applicable; NHS: National Health Services; PHLS: Public Health Laboratory Service; CDSC: Communicable Disease Surveillance Centre ; yrs: years</p>			

Author, journal, year, aim	Country, study design, study period and duration	Setting, source population, in/exclusion criteria, sample size, age, gender	Disease/Infectious agent, case definition, sampling, laboratory-methods
<p>Author: El-Radhi</p> <p>Journal: Arch Dis Child</p> <p>Pub Year: 1992</p> <p>Aim: To determine whether the observation that, among children with <i>Salmonella</i> gastroenteritis, those with a temperature greater than 40°C had a significantly shorter duration of bacterial excretion compared with afebrile children (from a study among 125 children in Kuwait), also holds for Finnish children with <i>Salmonella</i> gastroenteritis.</p>	<p>Country: Finland</p> <p>Study design: Case series</p> <p>Study period & duration: January 1974 to December 1990</p>	<p>Setting: Paediatric department of a hospital</p> <p>Source population: All children hospitalised at the paediatric department the Aurora hospital in Helsinki</p> <p>Inclusion criteria: *Gastroenteritis *Positive stool culture for non-typhoid <i>Salmonella</i></p> <p>Exclusion criteria: *Illness commenced in foreign countries *Children who were referred to the hospital after the diagnosis had been established</p> <p>Sample: *n=102 *Mean age: 5.6 yrs (range 3 months-15.5yr) *52.9% male</p>	<p>Disease/infectious agent: Non-typhoid <i>Salmonella</i>. <i>S. Typhimurium</i> (n=60), <i>S. enteritidis</i> (n=18), other <i>Salmonella</i> (n=24)</p> <p>Case definition: *Acute gastroenteritis; and *Positive stool culture for non-typhoid <i>Salmonella</i></p> <p>Sampling (specimen, frequency, duration): *Stools *Routine investigation during hospitalisation (frequency NR). After discharge, weekly. *Until bacteriological cure</p> <p>Lab method: Bacterial culture</p>
Outcome definition, results			Comments, limitations
<p>Outcome definition: Duration of shedding: From admission to hospital until bacteriological cure (at least three successive negative cultures)</p> <p>Results: Mean (± SD) days of shedding from admission to hospital - <i>S. Typhimurium</i>: 5.4 weeks (± 6.2) - <i>S. Enteritidis</i>: 3.8 weeks (± 3.7) - Other <i>Salmonella</i>: 5.4 weeks (± 13.6)</p>			<p>Comments: *Duration of excretion did not significantly differ between different <i>Salmonella</i> types *None of the children received antibiotics specifically aimed at <i>Salmonella</i> infection. Nine children received penicillin and six other children received various other antibiotics at the acute stage of illness *Significant correlation was found between the duration of convalescent excretion and fever at the initial stage of illness. The shortest mean duration of excretion was found in children with high fever on admission and the longest was in afebrile children</p> <p>Limitations: *Duration of shedding not calculated from time of onset of symptoms *Duration of diarrhea before admission to the hospital was unknown</p>
NR: not reported; SD: standard deviation; yrs: years.

Outcome definition, results			Comments, limitations
<p>Outcome definition: Incubation period: Time from consumption of infected meat until first symptoms</p> <p>Results: * Range: 5-34 days * < 8 days: 3 cases, 8-14 days: 25 cases, 15-21 days: 22 cases, 22-28 days: 4 cases, >28 days: 2 cases</p> <p>The incubation periods in 2 cases recorded as >28 days must be regarded as doubtful: both periods are calculated from dates on which they undoubtedly ate meat from the primary source, but each child was subsequently in contact with a proved case of the disease, and it is perhaps more likely that both were secondary cases with short incubation periods rather than primary cases.</p>			<p>Comments: * 58 cases were positive for blood culture and typhoid bacilli was isolated in stool samples among 41 cases * Incubation data do not include n=30 patients who are denoted as uncertain (source of infection unknown n=10, food bought from the shop on several occasions n=20)</p> <p>Limitations: * Chloramphenicol or ampicillin, or both drugs in sequence, were given upon hospital admission in every case, the primary course of treatment lasting 14 days except in 5 cases in which the course was extended for a max of 25 days</p>

<p>Author: Tauxe</p> <p>Journal: Am J Public Health</p> <p>Pub Year: 1986</p> <p>Aim: To examine the efficacy of different control strategies applied to simultaneous outbreaks of shigellosis in 2 day care centers</p>	<p>Country: United States</p> <p>Study design: Outbreak investigation</p> <p>Study period & duration: Outbreaks started in September 1983 (and lasted 21 and 34 days)</p>	<p>Setting: Day care centers</p> <p>Source population: Children and staff at the two day care centers, in Seattle, Washington</p> <p>Sample: *Center A: 80 children, 16 staff members; Center B: 23 children, 3 staff members. <i>S. sonnei</i> isolated from 24 children, staff and family members associated with the 2 centers. The yield of cultures among persons meeting the case definition was 63%. *Age: NR *Gender: NR</p>	<p>Disease/infectious agent: <i>Shigella sonnei</i></p> <p>Case definition: *Illness with diarrhea (≥ 3 loose stools in a 24-hour period) or with fever and abdominal pain or vomiting, occurring between September 5 and October 4. A child was considered to have diarrhea if either a parent or a day care employee reported it; or clinical symptoms and *<i>Shigella</i> isolated</p> <p>Sampling (specimen, frequency, duration): *Stools *NA</p> <p>Lab Method: Standard techniques</p>
Outcome definition, results			Comments, limitations
<p>Outcome definition: Exclusion period: Exclusion, isolation or closure until 2 negative successive stool cultures. The culture survey of 29 non-isolated children at center A, conducted 2 weeks after the establishment of the isolation room, identified 3 culture-positive children. 2/3 had had mild untreated diarrheal illness in September, and were counted as cases. 1/3 was an asymptomatic carrier. All 3 were ≥ 4 yrs of age; all were subsequently given antimicrobials without placing them in isolation.</p> <p>In both centers hand washing and careful cleansing of the diaper-changing area was stressed. A stool culture was obtained from each staff person; staff with diarrhea or a positive culture were excluded from work. Both day care centers were closed to new enrolment and symptomatic children were excluded. Parents were instructed to take their child to a physician for a stool culture if diarrhea developed, to use careful hygiene in the home, and not to place a child who had had diarrhea in any day care facility until 2 successive stool cultures were negative.</p> <p>Center A: Beginning October 3, 1983, an additional element in the control strategy was implemented. Children and staff with diarrhea from whom <i>Shigella</i> was isolated were allowed to return to the center of appropriate antimicrobial therapy after their diarrhea had ceased, but before negative follow-up cultures had been obtained; they were isolated in a separate room with its own bathroom, sink, and playground until all had had 2 negative stool cultures (21 days).</p> <p>Center B: <i>Shigella</i> had been isolated from the director and her 2 children, and the 2 other employees had diarrhea. The center closed voluntarily on October 4, 1983 and remained closed until the director and her family had had 2 successive negative stool cultures after antimicrobial therapy (34 days).</p> <p>Results: Transmission ceased at both centers within 2 days after intervention, and the outbreak did not spread to the rest of the community."</p>			<p>Comments: *Providing convalescent day care in isolation to children under therapy may offer several advantages compared to the strategies of closing the center, or of excluding ill children until they are culture-negative (less social impact as need for alternate day care was less; convalescent staff could return to work without waiting for negative cultures; may decrease contact between infected children and other children inside or outside center; parents have additional incentive to seek treatment if it permits them to return their children to day care sooner; treatment children receive can be documented and supervised; obtaining follow-up cultures simplified because the persons to be cultured are all in one place; strategy well received by parents of non-ill children; when a day care facility is closed or culture-positive convalescent children are excluded, infected children may often be cared for in a variety of settings even if they do not return to licensed day care, which may increase likelihood of spread of infection to community and other day care centers). *It is not clear that all convalescent children require isolation; they are likely to be culture-negative within days of starting appropriate antimicrobial therapy *Antimicrobial therapy itself may not be essential if careful isolation can be maintained. *The epidemiologic role played by asymptomatic <i>Shigella</i> excretors unknown, and it is not clear that they should be isolated.</p> <p>Limitations: *Several intervention strategies at once (including antimicrobial therapy)</p>

Author: Frank Journal: J Infect Dis Pub Year: 1981 Aim: To describe naturally acquired infections over a 4-yr period in children with mild to moderately severe illness.	Country: United States Study design: Prospective follow-up study Study period & duration: 1975 to 1979 (Influenza A), 1977 and 1980 (Influenza B)	Setting: Households Source population: Participants in the Houston Family Study (racially and socioeconomically mixed group residing in the Houston area) Inclusion criteria: *Families enrolled with the birth of a new infant *Influenza A or influenza B infection Sample: *n=70 families, including 80-100 children were followed at any one time. Influenza A illness: n=50 episodes (41 individual cases) Influenza B illness: n=14 episodes (14 individual cases) *Influenza A: children <4 years (except 2 children aged 6 yrs) Influenza B: children 0.5-10 yrs *Gender: NR	Disease/infectious agent: Influenza A, Influenza B Case definition: *Illness (not further specified); and *Virus-proven Sampling (specimen, frequency, duration): *Nasal washes or throat swabs *Weekly or biweekly, whether or not the child was ill; and additional specimens sometimes obtained due to presence of illness (in child or family member). For Influenza B in 1980 only: 2-3 times per week Lab method: CPE, hemadsorption, indirect immunofluorescence

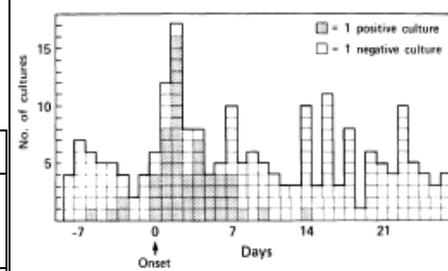

Outcome definition, results	Comments, limitations
-----------------------------	-----------------------

Outcome definition:
 Duration of shedding: Shedding during time between sampling (at set intervals) and onset of disease. Only isolates obtained <9 days before the onset were considered to be related to the subsequent illness and up to 40 days after onset of illness.

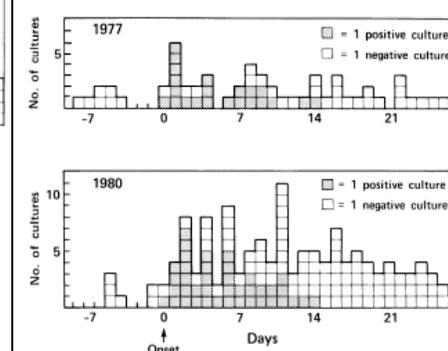

Results:
 *Table. Proportion of positive samples by day of onset of symptoms for influenza A and B

Days from onset of symptoms	Influenza A		Influenza B	
	Positive samples/ total samples	% positive samples	Positive samples/ total samples	% positive samples
Days -5 to -8	1/22	5%	0/9	0%
Days -1 to -4	3/15	20%	0/4	0%
Days 0 to 3	32/43	74%	23/29	79%
Days 4 to 7	19/27	70%	19/28	68%
Days 8 to 11	2/20	10%	15/36	42%
Days 12 to 15	1/19	5%	5/23	22%
Days 16 to 19	0/23	0%	0/27	0%
Days 20 to 23	0/25	0%	0/18	0%
Days 24 to 27	0/16	0%	0/13	0%

<p>Author: Jackson</p> <p>Journal: BMJ Open</p> <p>Pub Year: 2013</p> <p>Aim: To review the effects of school closures on pandemic and seasonal influenza outbreaks.</p>	<p>Country: Worldwide</p> <p>Study design: Systematic literature review</p> <p>Study period & duration: Search performed in January 2012, up until the end of 2011</p>	<p>Setting: Schools</p> <p>Source population: Medline and Embase; In addition, Eurosurveillance (23 April 2009 to 15 December 2011), Morbidity and Mortality Weekly Report (24 April 2009 to 23 December 2011) and Emerging Infectious Diseases (April 2009 to December 2011) were hand-searched. Results were supplemented using the reference lists of the articles identified and papers from the reviewers' collections. An additional PubMed search (for the words 'influenza' and 'school') was used to identify relevant papers published during October–December 2011 but not yet listed in MEDLINE or EMBASE</p> <p>Inclusion criteria: *Described one or more influenza outbreaks during which schools were initially open and subsequently closed, with or without other interventions *If papers presented several measures of influenza activity, the most specific data were extracted (eg, data on laboratory-confirmed influenza were extracted in preference to all-cause school absenteeism) *Studies using modelling techniques to assess how school closure affected transmission based on real epidemic curves were eligible</p> <p>Exclusion criteria: *Predictive modelling studies exploring how school closure might affect a hypothetical outbreak *Studies written in languages other than English *Studies of outbreaks which started during school closure</p> <p>Sample: 22 studies including 19 epidemic curves. Europe: n=6; Asia: n=7; Australasia: n=2; Americas: n=7</p>	<p>Disease/infectious agent: Influenza</p> <p>Case definition: *NA</p> <p>Sampling (specimen, frequency, duration): *NA</p> <p>Lab Method: NA</p>
Outcome definition, results			Comments, limitations
<p>Exclusion period: School closure, any duration</p> <p>Reduction in influenza transmission:</p> <p>Peak and cumulative attack rates (95% CI's); normalised peak (peak AR/median AR) for datasets with a median AR>0 (to adjust approximately for differences in case definitions and stratified by timing of closure); Association between school closure and outcome: usually comparison of cases before closure and after closure.</p> <p>Results:</p> <p>The results suggest that school closure can reduce transmission of seasonal influenza among school-children. However, many datasets show no clear effect of school closure, possibly because schools in these instances shut late in the outbreak. Incidence sometimes rebounded when schools reopened and this reversibility of effects may be seen as evidence for school closure causing reduction in incidence. Complicating factors were 1) the use of multiple interventions and 2) variation in case definition (from absenteeism to laboratory confirmation, being relatively non-specific and severe, respectively).</p>			<p>Comments: *Search terms are reported in supplementary material *The optimal school closure strategy does not become clear</p> <p>Limitations: NR</p>

<p>Author: Lamden</p> <p>Journal: Arch Dis Child</p> <p>Pub Year: 2010</p> <p>Aim: To describe an outbreak of scarlet fever in a primary school.</p>	<p>Country: England</p> <p>Study design: Outbreak investigation</p> <p>Study period & duration: March 2009 (4 weeks)</p>	<p>Setting: Primary school</p> <p>Source population: Pupils from a primary school in Lancashire</p> <p>For the epidemiological study potential cases were identified from the school absence register</p> <p>Sample: *n=57 cases (n=9 confirmed cases, n=12 probable and n=36 possible cases) *Age range: 4-11 yrs; mean: 8 yrs *M/F-ratio: 28/29</p>	<p>Disease/infectious agent: Group A <i>Streptococcus S. pyogenes</i> group B type emm3</p> <p>Case definition: *Cases were classified on the basis of microbiology and symptoms reported by parents to the school. Cases were defined as confirmed (clinical symptoms plus throat isolate of GABHS), probable (rash and none or negative throat swab) or possible (sore throat alone). *The clinical presentation included pharyngitis, flushed facial appearance with inflammation and soreness around the mouth, and an extensive florid rash. Not all children had a rash.</p> <p>Sampling (specimen, frequency, duration): *Throat swabs *NA</p> <p>Lab Method: NR</p>
Outcome definition, results			Comments, limitations
<p>Exclusion period: Exclusion of cases from school was rigorously enforced and although the minimum exclusion was 24 hours, in practice it was usually 48 hours</p> <p>Exclude symptomatic children from school until they had received at least 24 hours of penicillin treatment.</p> <p>Other control measures were: closure of water fountains, disinfection of children's water bottles, extra washing of toys, extensive promotion of hand-washing.</p> <p>Results: Ineffective, control measures had little impact on disease transmission. 57 out of 126 pupils developed scarlet fever -days absent from school: 1-10 (median, 3)</p>			<p>Comments: *GABHS type emm3 was isolated from 9/13 throat swabs obtained *Index case absent from school on March 3rd, report to CDC on March 10th, control measures in place with just 6 children unwell *37/57 received antibiotics</p> <p>Reasons for continuing transmission: -only 65% of cases received antibiotics. The advice was to prescribe antibiotics for 10 days; however 10-day course only prescribed in 54% of those receiving antibiotics. Additionally, there was possibly also lack of therapy compliance -carriers of GABHS in the school and household probably contributed to continuance, although it is also possible that cases in the wider community helped to sustain the outbreak</p> <p>Limitations: *Multiple interventions</p>
<p>CDC: center for disease prevention and control; GABHS: group A β-haemolytic <i>streptococcus</i>; M/F-ratio: male-to-female ratio; NR: not reported; yrs: years</p>			

Streptococcal pharyngitis (n=1)

	infected	96	4.0	3.3	4.9																																																																										

Mean: 7.69 days (95%CI 6.41-8.98) from symptom onset

For all children who did or did not attend the clinic (=with either known date of symptom onset or date of first sample)

*Range: 1-14 days from symptom onset or first sample

*Mean: 4.5 days (95% CI, 4.0-5.3) from symptom onset or first sample

*Median: 4 days (IQR 2-6) from symptom onset or first sample

Feature*		RR ^b	p-value	Lower CI	Upper CI
Revised history ^c	Infected	1.37	0.04	1.01	1.86
Sex	Female	0.86	0.33	0.64	1.16
Age group	12-17 months	1.01	0.98	0.57	1.76
	18-23 months	0.91	0.73	0.54	1.53
	24+ months	1.08	0.78	0.65	1.80
Severity	Mild LRTI	0.69	0.15	0.42	1.14
	Severe LRTI	0.82	0.62	0.38	1.80

*baseline for each comparison is: no history of infection, male sex, 0-11 month age group and URTI severity.

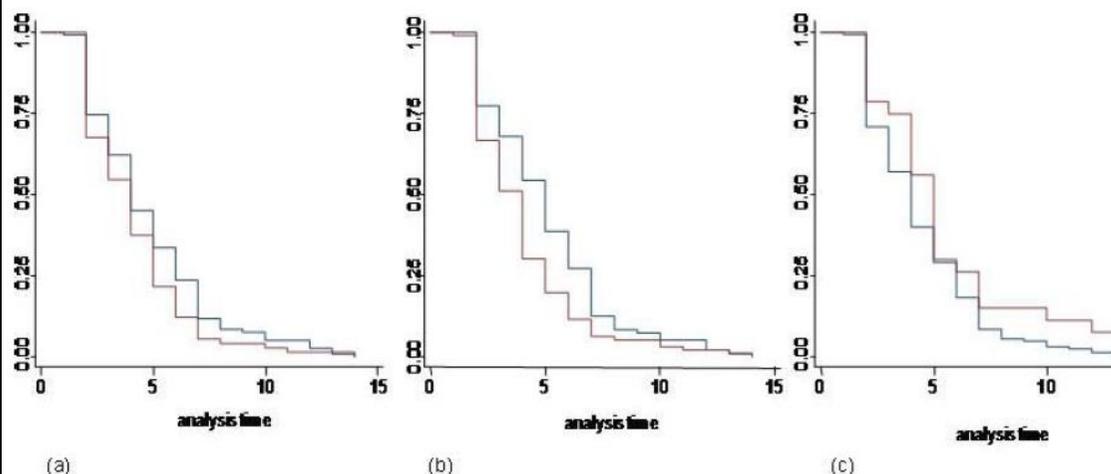

^bAll estimates are adjusted for all other factors.

^cAssumes children over 3 years (greater than 36 months old) have been previously infected.

Limitations:

- *Data are subject to left censoring as exact start time of shedding was not observed.
- *For the non-clinic cases, shedding not measured from time of symptom onset
- *Duration of shedding may have been underestimated by taking the first negative test to indicate cessation of shedding
- *More sensitive detection techniques such as PCR might be warranted
- *Viral load was not quantified. Quantification of viral load might have epidemiological consequences for transmission potential

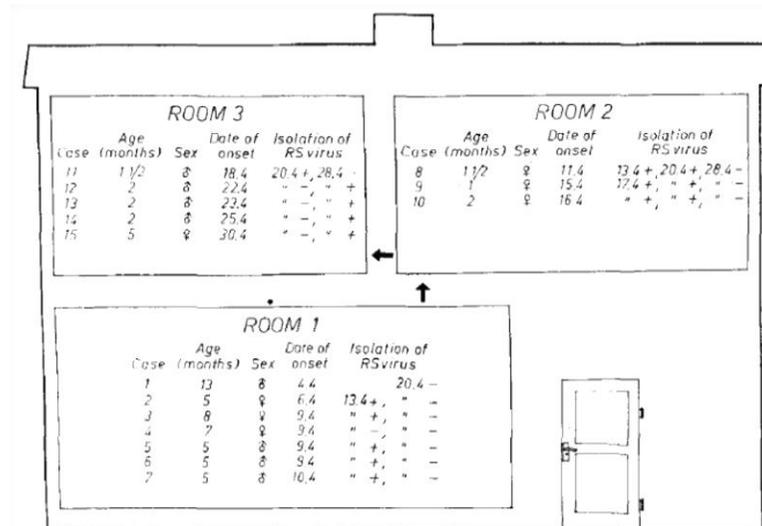

*Figure 2. Kaplan-Meier survivor function plots for cessation of shedding of RSV in infected Kenyan children. Results are categorised by age class (blue: 0-23 months; maroon: 24+ months) in Graph a, by infection history (blue: never infected; maroon: infected-significantly different; log rank test p < 0.05) in Graph b, and by severity (blue: URTI; maroon: LRTI) in Graph c.

ARI: acute respiratory illness; CI: confidence interval; IQR: interquartile range; LRTI: lower respiratory tract infection; M/F-ratio: male-to-female ratio; PCR: polymerase chain reaction; RSV: respiratory syncytial virus; URTI: upper respiratory tract infection; yrs: years

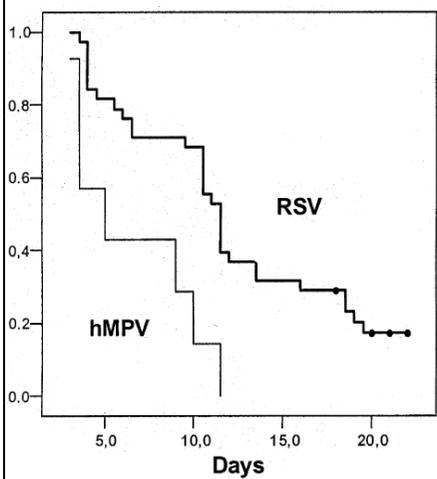

Author, journal, year, aim	Country, study design, study period and duration	Setting, source population, in/exclusion criteria, sample size, age, gender	Disease/Infectious agent, case definition, sampling, laboratory-methods
Author: Sterner Journal: Acta Paediatr Scand Pub Year: 1966 Aim: To present virological, epidemiological and clinical findings during an outbreak of RSV infections in a home for infants in Stockholm.	Country: Sweden Study design: Outbreak investigation Study period & duration: Between April and May 1964	Setting: Home for infants Source population: All infants at a home for infants, in Stockholm Inclusion criteria: *Ill with acute respiratory disease *Laboratory-confirmed RSV Sample: *n=15 infants; RSV was isolated in n=13 *Age range: 1-13 months *M/F-ratio: 8/7	Disease/infectious agent: RSV Case definition: *Clinical symptoms with acute respiratory diseases (signs of acute respiratory illness, with rhinitis, pharyngitis, and a cough which was slightly hoarse) *Confirmed with culture of HeLa cells, serum testing of CF antibody and bacterial study to rule out pneumococci, streptococci, <i>Staphylococcus aureus</i> and <i>Haemophilus influenza</i> Sampling (specimen, frequency, duration): *Pharynx and nasopharynx swabs *2 or 3 times, 1 week apart Lab Method: Culture of HeLa cells, isolate typing by complement fixation or neutralisation against test sera from guinea pigs

Outcome definition, results	Comments, limitations
-----------------------------	-----------------------

Outcome definition: Duration of shedding: Time span during which shedding took place Results: RSV was isolated during a period from 2 days before to 9 days after onset of illness	*Figure. Age, sex, date of onset of illness and virus findings in 15 children with RS  <p style="text-align: center;">virus infection</p>	Comments: NR Limitations: *The incubation period appeared to be from 3-5 days, but unclear how this was calculated
---	---	---

CF: complement fixation; M/F-ratio: male-to-female ratio; NR: not reported; RSV: respiratory syncytial virus
