## SURVEILLANCE REPORT

# Influenza virus characterisation 

## Summary

Over the course of the 2014-15 influenza season influenza A(H3N2), A(H1N1)pdm09 and type B viruses have cocirculated in EU/EEA countries. To date, 23 EU/EEA countries have shared 810 influenza-positive specimens with the WHO Collaborating Centre in London for detailed characterisation. Since the April 2015 report ${ }^{1}, 62$ viruses have been characterised antigenically and 58 genetically.
The 19 A(H1N1)pdm09 viruses characterised antigenically were similar to the vaccine virus A/California/07/2009; all 16 characterised genetically had HA genes belonging to genetic subgroup 6B, as observed worldwide.

All 21 A(H3N2) viruses characterised by haemagglutination inhibition (HI) assay were poorly recognised by antisera raised against the $A / T e x a s / 50 / 2012$ vaccine virus but relatively well recognised by antisera raised against cellpropagated genetic subgroup 3C.3a viruses. The 298 ( 31 since the April 2015 report) viruses, with collection dates after 31 August 2014, characterised genetically this season fell in genetic group/subgroups 3C.3 (33), 3C.3b (61), 3C.3a (34) and 3C.2a (170). Viruses in genetic group 3C. 3 and subgroup 3C.3b were antigenically similar to A/Texas/50/2012, while those in subgroups 3C.2a and 3C.3a were antigenically distinct, and the two subgroups were antigenically distinguishable.
No B/Victoria-lineage viruses were received since the April 2015 report.
The 22 characterised $B /$ Yamagata-lineage test viruses fell in genetic clade 3 and showed good reactivity with antisera raised against $\mathrm{B} /$ Phuket/3073/2013 (the clade 3 virus recommended for the southern hemisphere 2015 and northern hemisphere 2015-16 vaccines). Antisera raised against B/Massachusetts/02/2012 (the clade 2 virus recommended for the 2014-15 northern hemisphere season vaccine) did not recognise test viruses as well as antisera raised against B/Phuket/3073/2013.

[^0][^1]Influenza-positive samples ( 810 viruses or clinical specimens: five being received since the April 2015 report), with collection dates after 31 August 2014, were received at the Crick Worldwide Influenza Centre, the Francis Crick Institute, Mill Hill Laboratory, from 23 countries in the EU/EEA. Overall, the majority ( $\sim 80 \%$ ) were type A viruses, and $A(H 3 N 2)$ outnumbered $A(H 1 N 1)$ pdm09 at a ratio of > 3:1 (Table 1). Of the 168 type B specimens received ( $\sim 20 \%$ of the specimens), 129 were of the B/Yamagata-lineage, 36 were not ascribed to a lineage, and only three were of the $B /$ Victoria lineage. Some of these samples, mostly received as clinical specimens, are still in the process of being characterised. The antigenic and genetic properties of influenza virus isolates characterised since the April 2015 report are presented and discussed in this report.

Table 1. Summary of clinical samples and virus isolates received from EU/EEA Member States, with collection dates after 31 August 2014

## Influenza A(H1N1)pdm09 virus analyses

Haemagglutination inhibition (HI) analyses of viruses that have been performed since the April 2015 report are shown in Table 2. Eighteen of 19 recovered $\mathrm{A}(\mathrm{H} 1 \mathrm{~N} 1)$ pdm09 viruses, all from Italy, were antigenically similar to the vaccine virus, A/California/7/2009, showing no more than twofold reduction in HI titre compared to that for the homologous virus, while A/Perugia/41/2015 showed a fourfold reduction and carried HA1 amino acid substitution (D127E) and polymorphism (D222G/D): the lowest titres for all antisera in the panel were recorded with this virus.

All viruses were recognised by the extended panel of antisera at titres within fourfold of the titres for the homologous viruses, with the exception of the antiserum raised against $\mathrm{A} /$ Christchurch/16/2010. This antiserum recognised $37 \%(7 / 19)$ of the test viruses at a titre within fourfold of the titre for the homologous virus. It is also noteworthy that all antisera raised against viruses falling outside of genetic group 1, the A/California/7/2009 group, recognised the egg-propagated vaccine virus at titres at least eightfold reduced compared to the titres of the antisera with their homologous viruses.

Figure 1 shows a phylogenetic tree for the HA genes of representative, recently circulating A(H1N1)pdm09 viruses. Since 2009, the HA genes have evolved, and eight genetic groups have been designated. Over the last two seasons, viruses in genetic group 6, represented by A/St Petersburg/27/2011 and carrying amino acid substitutions of D97N, S185T and S203T in HA1 and E47K and S124N in HA2 compared with A/California/7/2009, have predominated worldwide, with a number of subgroups emerging. All EU/EEA viruses characterised since the September 2014 report $^{2}$ carry HA genes in genetic subgroup 6B, which is characterised by additional amino acid substitutions of K163Q, A256T and K283E in HA1 and E172K in HA2 compared with A/California/7/2009, e.g. A/South Africa/3626/2013.
These results are compatible with those that contributed to the World Health Organization recommendation ${ }^{3}$ to retain the A/California/7/2009 vaccine virus for the northern hemisphere 2015-16 influenza season.

## Influenza A(H3N2) virus analyses

As described in many previous reports ${ }^{4}$, influenza A(H3N2) viruses continue to be difficult to characterise antigenically by HI assay due to variable agglutination of red blood cells (RBCs) from guinea pigs, turkeys and humans or the loss of the ability of viruses to agglutinate any of the RBCs. This is a particular problem for most viruses that fall in genetic subgroup 3C.2a, as was highlighted in the November 2014 report $^{5}$.
Results of HI tests performed with guinea pig RBCs in the presence of 20 nM oseltamivir, added to circumvent any NA-mediated binding of A(H3N2) viruses to the RBCs, conducted since the April 2015 report are shown in Tables 3-1 and 3-2. The HA genetic group is indicated for those viruses that have been sequenced, and those included in the HA phylogenetic tree (Figure 2 ) are highlighted. Of the 70 successfully propagated viruses, only 21 (30\%) retained sufficient HA titre to be analysed by HI assay, a proportion similar to that in the April 2015 report. The remainder $(\mathrm{n}=49)$ were either unable to agglutinate guinea pig RBCs at all or were unable to agglutinate RBCs in the presence of 20nM oseltamivir. The vast majority of viruses unable to be titred by HI that were subjected to genetic analysis belonged to genetic subgroup 3C.2a. Viruses in genetic subgroup 3C.2a have acquired a glycosylation motif at positions 158 to 160 in HA1; those viruses in genetic subgroup 3C.2a that were able to bind guinea pig RBCs in the presence of oseltamivir (and hence were analysed by HI assay) had either lost, or were polymorphic for, this glycosylation motif.
All 21 test viruses, propagated in MDCK-SIAT1 cells, reacted poorly in HI assays ( $\geq$ eightfold decrease) with postinfection ferret antiserum raised against the egg-propagated vaccine virus, $A / T e x a s / 50 / 2012$, compared to the titre of the antiserum with the homologous virus. Similarly, low levels of reactivity were seen with antisera raised against the egg-propagated reference virus A/Hong Kong/146/2013: no test virus reacted within fourfold of the titre with the homologous egg-propagated virus. Better reactivity was seen with test viruses when analysed with an antiserum raised against the exclusively egg-propagated A/Stockholm/6/2014 isolate 2, a virus belonging to genetic subgroup 3C.3a. This antiserum showed a low titre for the homologous virus but recognised all test viruses at titres within fourfold of the homologous titre. Antiserum raised against egg-propagated A/Switzerland/9715293/2013, the virus in genetic subgroup 3C.3a recommended for the southern hemisphere 2015 and northern hemisphere 2015-16 vaccines, gave homologous titres of 640-1280 and did not recognise any of the test viruses at titres within fourfold of the homologous titre. Similarly, antiserum raised against eggpropagated A/Hong Kong/5738/2014 clone 121, a virus in genetic subgroup 3C.2a, failed to recognise any of the test viruses at titres within fourfold of the homologous titre.

Ferret antisera raised against reference viruses propagated in tissue culture cells, A/Victoria/361/2011 and A/Samara/73/2013, recognised the test viruses somewhat more effectively. The antiserum raised against A/Victoria/361/2011 recognised $\sim 95 \%$ of the test viruses at a titre within fourfold of the antiserum for the homologous virus, but the antiserum raised against A/Samara/73/2013 recognised only $\sim 48 \%$ of test viruses at a titre within fourfold of the titre for the homologous virus. These reference viruses have HA genes from genetic groups 3C. 1 and 3C.3, respectively. Antisera raised against reference viruses belonging to genetic subgroup 3C.3a that had been exclusively propagated in cell culture, A/Stockholm/6/2014 and A/Switzerland/9715293/2013, both recognised approximately $86 \%$ of test viruses at titres within fourfold of those with the corresponding homologous viruses. An antiserum raised against a reference virus belonging to genetic subgroup 3C.2a that had been exclusively propagated in cell culture, A/Hong Kong/5738/2014, recognised all test viruses at titres within fourfold of that for the homologous virus.

[^4]Since 2009, seven genetic groups based on the HA gene have been defined for A(H3N2) viruses. Phylogenetic analysis of the HA genes of representative, recently circulating A(H3N2) viruses is shown in Figure 2. The HA genes fall within genetic group 3C. This group has three subdivisions: 3C. 1 (to which the recommended vaccine virus for the 2014-15 northern hemisphere season, A/Texas/50/2012, belongs), 3C. 2 and 3C.3. Viruses in these three subdivisions have been antigenically similar. However, in 2014 three new genetic subgroups emerged, one in subdivision 3C.2, 3C.2a, and two in 3C.3, 3C.3a and 3C.3b (Figure 2). While viruses in genetic subgroups 3 C .2 a and 3 C .3 a are antigenic drift variants, those in 3C.3b have remained antigenically similar to previously circulating viruses in the 3C. 3 subdivision. Amino acid substitutions that define these subdivisions and subgroups compared with A/Texas/50/2012 are:

- (3C.2) N145S and V186G ${ }^{6}$ in HA1, and D160N in HA2, e.g. A/Hong Kong/146/2013
- (3C.2a) Those in 3C. 2 plus L3I, N144S (resulting in the loss of a potential glycosylation site), F159Y, K160T (in the majority of viruses, resulting in the gain of a potential glycosylation site), N225D and Q311H in HA1, e.g. A/Hong Kong/5738/2014
- (3C.3) T128A (resulting in the loss of a potential glycosylation site), R142G, N145S and V186G in HA1, e.g. A/Samara/73/2013
- (3C.3a) those in 3C. 3 plus A138S, F159S and N225D in HA1, many with K326R, e.g. A/Switzerland/9715293/2013
- (3C.3b) those in 3C. 3 plus E62K, K83R, N122D (resulting in the loss of a potential glycosylation site), L157S and R261Q in HA1 with M18K in HA2, e.g. A/Newcastle/22/2014

Of the A(H3N2) viruses received from EU/EEA countries, with collection dates since 31 August 2014, 298 have been characterised genetically. These have fallen in HA genetic subgroups $3 C .2 a(n=170 ; 57 \%), 3 C .3 a(n=34 ;$ $11 \%$ ) and 3C.3b ( $\mathrm{n}=61 ; 21 \%$ ), with the remainder ( $\mathrm{n}=33 ; 11 \%$ ) being in subdivision 3C.3. This is indicative of $67 \%$ of recently circulating $A(H 3 N 2)$ viruses being antigenic drift variants compared to $A / T e x a s / 50 / 2012$, the virus recommended for use in northern hemisphere 2014-15 vaccines.

Based on results that showed cross-reactivity of antisera raised against genetic subgroup 3C.3a and 3C.2a viruses but with issues of antigenic changes on egg-adaptation of genetic subgroup 3C.2a viruses, the World Health Organization recommendation was to use an A/Switzerland/9715293/2013-like virus as the A(H3N2) component of vaccines for the northern hemisphere 2015-16 influenza season.

## Influenza B virus analyses

Influenza B viruses represented just over 20\% of samples received from EU/EEA countries with collection dates after 31 August 2014 (Table 1). Of the 132 viruses ascribed to a lineage, B/Yamagata viruses predominated over those of $\mathrm{B} /$ Victoria at a ratio of 43:1.

## Influenza B - Victoria lineage

No viruses of this lineage have been received since the April 2015 report.
Phylogenetic analysis of the HA gene of representative, recently collected B/Victoria lineage viruses based on sequences available in GISAID, with collection dates since 1 January 2015, is shown in Figure 3. Worldwide, recent viruses have HA genes that fall into the $B / B r i s b a n e / 60 / 2008$ genetic clade (clade $1 A$ ) and remain antigenically similar to the recommended vaccine virus, $B /$ Brisbane/60/2008, for use in quadrivalent vaccines. $B /$ RheinlandPfalz/1/2014, which clusters closely with B/Brisbane/60/2008 in the phylogenetic tree, was isolated from a child recently vaccinated with a live attenuated influenza vaccine. Compared to the phylogenetic analysis presented in the April 2015 report, containing viruses with collection dates up to the end of December 2014, there has been a change in prevalence of genetic subgroup from that defined by HA1 amino acid substitution K209N (e.g. B/BadenWürttemberg/3/2014) to that defined by N129D substitution (e.g. B/Iceland/63/2014) based on viruses collected in the USA and Japan.

## Influenza B - Yamagata lineage

HI results for the 22 B/Yamagata-lineage test viruses, from Italy and Spain, analysed since the April 2015 report are shown in Tables 4-1 and 4-2. All eight test viruses for which HA gene sequencing has been completed fell in genetic clade 3, and these sequences are included in the phylogenetic tree (Figure 4).
Post-infection ferret antiserum raised against the egg-propagated vaccine virus B/Massachusetts/02/2012, recommended for use in the 2014-15 northern hemisphere influenza season, recognised $27 \%$ (6/22) of test viruses at titres within fourfold of the titre with the homologous virus. A ferret antiserum raised against a cell culture-propagated cultivar of $B / M a s s a c h u s e t t s / 02 / 2012$ recognised $77 \%(17 / 22)$ of test viruses at titres within fourfold of its titre with the homologous virus. Antisera raised against cell culture-propagated B/Estonia/55669/2011 and belonging to the B/Massachusetts/02/2012 clade (clade 2) recognised $64 \%(14 / 22)$ of the test viruses at titres within fourfold of the titres of the antisera with the homologous virus.
An antiserum raised against a previously recommended vaccine virus, $B /$ Wisconsin/1/2010, recognised all 22 test viruses at titres within fourfold of the titre with the homologous virus, as was the case for $95 \%(21 / 22)$ of test viruses with an antiserum raised against egg-propagated $B /$ Stockholm/12/2011, a virus also belonging to clade 3 represented by $B /$ Wisconsin $/ 1 / 2010$ and $B /$ Phuket/3073/2013. Similarly, all test viruses were recognised well by antisera raised against recent egg-propagated viruses compared to their respective homologous titres: within fourfold for that raised against B/Phuket/3073/2013, the virus recommended as a vaccine virus for the southern hemisphere 2015 and northern hemisphere 2015-16 influenza seasons, and within twofold for that raised against B/Hong Kong/3417/2014. Antiserum raised against a cell culture-propagated cultivar of B/Phuket/3073/2013 recognised $86 \%(19 / 22)$ of test viruses at titres within fourfold of the titre for the homologous virus. Based on HI titre fold-drop, antisera raised against the egg-propagated clade 3 viruses, which include previous
(A/Wisconsin/1/2010) and recently recommended (A/Phuket/3073/2013) vaccine viruses, are more reactive with currently circulating clade 3 viruses than antisera raised against the egg-propagated clade 2
$\mathrm{B} /$ Massachusetts/02/2012 vaccine virus used in the northern hemisphere 2014-15 influenza season.
Figure 4 shows a phylogenetic analysis of the HA genes of representative B/Yamagata-lineage viruses. Worldwide, the vast majority of HA genes from recently collected viruses have fallen in the B/Wisconsin/1/2010B/Phuket/3073/2013 clade (clade 3), with the great majority falling in a subgroup defined by HA1 L172Q amino acid substitution. A small proportion of viruses, detected in many parts of the world, have HA genes of clade 3 of the B/Yamagata lineage combined with NA genes of the B/Victoria lineage. A small group of viruses that are antigenically distinguishable from the great majority of clade 3 viruses, designated as clade 3a, have been detected in Australia.

## Summary of genetic data submitted to TESSy

As of 17 May 2015 (to week 20/2015), the majority of influenza viruses identified genetically since week 40/2014 were $A(H 3 N 2)$ viruses ( $60 \%$ ), with lower numbers of influenza B viruses (23\%) and $A(H 1 N 1)$ pdm09 viruses (17\%) being reported. This compares to proportions of $61 \%, 22 \%$ and $17 \%$, respectively, as of 3 May 2015 (see April 2015 report).
All influenza $A(H 1 N 1) p d m 09$ viruses fell into genetic clade 6, with the great majority ( $98 \%$ ) falling in genetic subgroup $6 B$, represented by $A /$ South Africa/3626/2013. Influenza $B$ viruses of the $B / Y a m a g a t a$ lineage outnumbered those of the $B /$ Victoria lineage by 41 to 1 . The majority of influenza $A(H 3 N 2)$ viruses belonged to genetic subgroup 3C.2a (62\%), represented by A/Hong Kong/5738/2014; smaller proportions were in genetic group 3C. 3 (30\%), represented by A/Samara/73/2013, genetic subgroup 3C.3a ( $<7 \%$ ), represented by A/Switzerland/9715293/2013, genetic group 3C.2, represented by A/Stockholm/1/2013 (< 1\%), and genetic subgroup 3C. 1 (1\%), represented by A/Texas/50/2012, the vaccine virus for the 2014-15 northern hemisphere influenza season. For EU/EEA countries, similar proportions have been observed among the influenza-positive samples shared with the WHO CC, except for the small number of A(H3N2) subgroup 3C. 1 detections.

## Antiviral susceptibility

Between weeks 40/2014-20/2015, based on reports to TESSy, 2616 influenza viruses (1535 A(H3N2), 566 A(H1N1)pdm09 and 515 type B) were subjected to phenotypic or genotypic testing for neuraminidase inhibitor (NAI) susceptibility. Four A(H3N2) viruses showed reduced susceptibility to oseltamivir, with three viruses carrying NA E119V amino acid substitution and one carrying NA R292K substitution. The latter virus showed reduced susceptibility to zanamivir. Two A(H1N1)pdm09 viruses showed reduced susceptibility to oseltamivir.

A total of 663 viruses, with collection dates after 31 August 2014, from EU/EEA countries have been assessed phenotypically for NAI susceptibility at the London WHO CC: 126 influenza $\mathrm{B}, 127 \mathrm{~A}(\mathrm{H} 1 \mathrm{~N} 1) \mathrm{pdm} 09$ and 410 A(H3N2), inclusive of many 3C.2a genetic subgroup viruses that could not be analysed by HI assay. All but one influenza B/Yamagata-lineage virus were susceptible to oseltamivir and zanamivir. The B/Yamagata-lineage virus showed reduced inhibition by oseltamivir and zanamivir, and carried NA amino acid substitution D197G.

## Influenza A(H7N9) virus

On 1 April 2013, the World Health Organization (WHO) Global Alert and Response [1] reported that the China Health and Family Planning Commission notified the WHO of three cases of human infection with influenza A(H7N9). The cases were confirmed by laboratory testing on 29 March 2013 by the Chinese CDC. A description of the characteristics of H7N9 viruses can be found on the WHO website [2]. Increased numbers of cases were reported over the course of the 2013-14 and 2013-14 seasons. A revised Rapid Risk Assessment [3] for these A(H7N9) viruses was carried out by ECDC and posted on 2 February 2015. WHO posted a summary of human infection on 31 January 2014 [4] and conducted a new risk assessment on 23 February 2015 [5]. In light of the assessment, WHO advised that countries continue to strengthen influenza surveillance. WHO last summarised the numbers of cases of human infection related to their geographic location on 14 July 2014 [6] and has provided subsequent situation updates, the latest one dated 14 May 2015 [7].

## Influenza A(H5N1) virus

The most recent monthly risk assessment of influenza at the human-animal interface was published by WHO on 1 May 2015 [8]. The assessment included a description of a further 13 new laboratory-confirmed human cases of avian influenza $\mathrm{A}(\mathrm{H} 5 \mathrm{~N} 1)$ virus infection in Egypt, including one fatality, and one new case in China. This represents a reduced number of new cases compared with earlier recent reports. ECDC published an updated Rapid Risk Assessment on the situation in Egypt on 13 March 2015 [9] and an epidemiological update on 10 April 2015 [10].

## WHO CC reports

A description of results generated by the WHO Collaborating Centre for Reference and Research on Influenza at the Crick Worldwide Influenza Centre, the Francis Crick Institute, Mill Hill Laboratory in London, and used at the WHO Vaccine Composition Meetings held at WHO Geneva on 22-24 September 2014 and 23-25 February 2015, can be found at:

## Note on the figures

The phylogenetic trees were constructed using RAxML, drawn using FigTree, and annotated using Adobe Illustrator. The bars indicate the proportion of nucleotide changes between sequences. Reference strains are viruses to which post-infection ferret antisera have been raised. The colours indicate the month of sample collection. Isolates from WHO National Influenza Centres in EU/EEA countries are marked '\#', as are those viruses for which data are presented in the HI tables (@). Sequences for some viruses from non-EU/EEA countries were recovered from GISAID. We gratefully acknowledge the authors, originating and submitting laboratories of the sequences from GISAID's EpiFlu database which were downloaded for use in the preparation of this report (all submitters of data may be contacted directly via the GISAID website), along with all laboratories that submitted sequences directly to the London WHO Collaborating Centre.

[^2]:    1. Propagated to sufficient titre to perform H assay (the totalled number does not include any from batches that are in process)
    2. Propagated to sufficient titre to perform Hl assay in presence of 20 nM oseltamivir (the totalled number does not include any from batches that are in process)

    Numbers in parentheses indicate viruses recovered but with insufficient HA titre to permit HI assay
