
SURVEILLANCE REPORT

Influenza virus characterisation

Summary Europe, June 2013

Summary

Over the course of the 2012–13 season, A(H1N1)pdm09, A(H3N2) and B/Victoria- and B/Yamagata-lineage influenza viruses have co-circulated in ECDC-affiliated countries. The relative prevalences of each has varied between countries.

- Type A and type B viruses have been detected in similar proportions but with type A peaking and declining slightly before type B.
- A(H1N1)pdm09 viruses have been detected at approximately twice the level of A(H3N2) viruses.
- The vast majority of A(H1N1)pdm09 viruses have remained antigenically similar to the vaccine virus, A/California/07/2009, but continued to show genetic drift with an increasing prevalence of genetic group 6 viruses.
- The vast majority of A(H3N2) viruses have been antigenically and genetically similar to cell-propagated A/Victoria/361/2011, the prototype vaccine virus for the 2012–13 influenza season.
- Viruses of the B/Yamagata-lineage have predominated over those of the B/Victoria-lineage.
- B/Victoria-lineage viruses have remained antigenically similar to cell-propagated reference viruses of the B/Brisbane/60/2008 genetic clade.
- B/Yamagata-lineage viruses formed two antigenically distinguishable genetic clades: clade 3 represented by B/Wisconsin/1/2010 (the recommended vaccine component for the 2012–13 influenza season) and, in increasing numbers, clade 2 represented by B/Massachusetts/2/2012 (the recommended vaccine component for the 2013–14 influenza season).

Viruses from specimens collected between 1 January 2013 and 31 May 2013, spanning the peak of the 2012–13 season, were received from 25 countries in the EU/EEA region at the MRC National Institute for Medical Research, WHO Collaborating Centre for Reference and Research on Influenza. A summary of specimens received is shown in Table 1.

The overall proportions of influenza type A (59%) and type B (41%) viruses received have become more similar, reflecting the decreasing proportion of influenza A towards the end of the season at the same time as the numbers of influenza virus detections were also falling. For type A, H1N1pdm09 viruses were received in greater numbers than H3N2 viruses (ratio 2:1). Among influenza B receipts, viruses of the B/Yamagata and B/Victoria lineages were received at a ratio of 4:1.

This report was prepared by Rod Daniels, Vicki Gregory and John McCauley on behalf of the European Reference Laboratory Network for Human Influenza (ERLI-Net), under contract to the European Centre for Disease Prevention and Control (ECDC).

1. Propagated to sufficient titre to perform HI assay (the totalled number does not include any from batches that are in process)
2. Propagated to sufficient titre to perform HI assay in presence of 20nM oseltamivir (the totalled number does not include any from batches that are in process)

Influenza A(H1N1)pdm09 virus analyses

The results of HI assays carried out on influenza A(H1N1)pdm09 viruses since the May report [1] are shown in Table 2. All but one test virus, A/Hungary/02/2013, showed good reactivity with post-infection ferret antisera raised against the panel of reference viruses, including antiserum raised against the vaccine virus, A/California/7/2009, with this antiserum recognising the test viruses shown at titres within fourfold of its recognition of the homologous virus. As described previously [2], antiserum raised against A/Christchurch/16/2010, a virus from a genetic group not seemingly in circulation at present (group 4), reacted less well than the other antisera with the test viruses: this ferret antiserum reacted with 14 of the 15 test viruses, with titres reduced eightfold or greater compared with the titre of the antiserum with the homologous virus.

Antisera raised against several of the reference viruses reacted poorly with A/Hungary/02/2013, showing eightfold or greater reductions in titre compared to the titres of the antisera with their homologous antigens; HA gene sequencing of this virus showed that it carried a N156D substitution in HA1. Amino acid substitution or polymorphism in the 153–157 region of HA1 can affect the antigenicity of the virus and commonly emerges during propagation of viruses in cell culture. A/Hungary/02/2013, but for its reactivity with antiserum raised against the vaccine virus (A/California/7/2009), shows a similar HI reactivity profile to the reference virus A/Bayern/69/2009, which carries G155E substitution in HA1. The effect of G155E substitution is less pronounced in the A/Lviv/N6/2009 reference virus, which contains an additional D222G HA1 substitution that is known to alter the receptor-binding properties of HA.

Phylogenetic analysis of the HA gene of representative viruses (Figure 1) shows that the H1N1 viruses from EU/EEA countries collected during the 2012–13 season cluster within genetic groups 6 and 7, with viruses belonging to group 6 predominating, notably so for those with collection dates since 1 March 2013. HA gene sequencing was performed on five test viruses, and their genetic grouping is shown in Table 2; all were in genetic group 6.

Influenza A(H3N2) virus analyses

Influenza A(H3N2) viruses continue to be difficult to characterise antigenically by HI assay due to variable agglutination of red blood cells from guinea pigs, turkeys and humans as described before [2]. The change in agglutination of red blood cells is associated with a reduced avidity of H3N2 viruses for the sialic acid receptor on the surface of the cell (Lin et al. 2012) [4]. Antigenic analyses of recently collected viruses conducted since the May report [1] are shown in Table 3. HI assays were carried out using guinea pig red blood cells in the presence of 20nM oseltamivir, added to circumvent the NA-mediated binding of H3N2 viruses to the red blood cells (Lin et al. 2010) [5]. The test viruses reacted poorly with post-infection ferret antiserum raised against the egg-propagated vaccine virus for 2012–13, A/Victoria/361/2011, compared with the titre against the homologous virus.

Generally, the test viruses also reacted poorly with antisera raised against other reference viruses and previous vaccine viruses propagated in eggs (A/Perth/16/2009, A/Victoria/208/2009, A/Iowa/19/2010 and A/Hawaii/22/2012). However, overall the panel of test viruses showed better reactivity with antiserum raised against egg-propagated A/Texas/50/2012 (the H3N2 vaccine virus recommendation for the northern hemisphere 2013–14) [6], compared with the titre of the antiserum with the homologous virus, than they did against other egg-propagated viruses. In Table 3, antiserum raised against A/Texas/50/2012 recognised 16 out of 19 test viruses at titres within fourfold of the titre to the homologous virus.

The test viruses reacted well with antisera raised against reference viruses exclusively propagated in in MDCK cells, and/or the derivative MDCK-SIAT-1 cells, when compared to the titres with the homologous viruses. These antisera were raised against cell-propagated virus isolates of A/Victoria/361/2011, A/Alabama/5/2010, A/Stockholm/18/2011, A/Berlin/93/2011 and A/Athens/112/2012.

Phylogenetic analysis of the HA gene sequences of representative viruses is shown in Figure 2. Viruses from EU/EEA countries collected since 1 January 2013 have HA genes that fall predominantly into genetic group 3C as is the case for all 13 test viruses sequenced during the preparation of this current report. Viruses carrying HA genes falling into group 3A and 3B (described in previous reports), 5 (e.g. A/Plzen/22/2013) and 6 (e.g. A/Lisboa/SU91/2012) have also been isolated earlier in the EU/EEA 2012–13 influenza season.

The amino acid substitutions in **HA1/HA2** associated with these groupings of recently collected viruses are:

- Group 3 viruses: **N145S** and **V223I**, with viruses in Groups 3B and 3C also carrying **A198S**, **N312S**; and in
- Group 3C: **S45N** (resulting in gain of a potential glycosylation site) and **T48I**, e.g. the prototype vaccine virus A/Victoria/361/2011; the great majority of viruses also carry the substitutions **Q33R** and **N278K** (e.g. A/Berlin/93/2011); an emerging subgroup also carries the substitutions **T128A** (resulting in the loss of a potential glycosylation site) and **R142G**;
- Group 3B: **D158N**;
- Group 3A: **N144D**, **D158N**;
- Group 5 viruses: **D53N**, **Y94H**, **I230V** and **E280A** (e.g. A/Alabama/05/2010), often in combination with **K2E**, **N8D** (resulting in the loss of a potential glycosylation site);
- Group 6 viruses: **D53N**, **Y94H**, **S199A, I230V** and **E280A** (e.g. A/Iowa/19/2010).

There is no evidence for antigenic change associated with any of the genetic groups or emerging subgroups, including the emerging subgroup in group 3C that carries substitutions in HA1 at amino acid residues 128 and 142.

Influenza B virus analyses

B/Victoria-lineage viruses

Table 4 shows the results of antigenic analyses for viruses of the B/Victoria-lineage performed since the May report [1]. All test viruses were from Hungary. Compared with the titre against the homologous virus in HI assays only one test virus, B/Hungary/05/2013, showed poor reactivity with post-infection ferret antiserum raised against the egg-propagated virus B/Brisbane/60/2008, a component of trivalent vaccines for the 2010–11 season and a recommended component of quadrivalent vaccines [6] for the 2013–14 northern hemisphere influenza season.

B/Hungary/05/2013 showed similarly reduced reactivities with antisera raised against other reference viruses propagated in hens' eggs: B/England/393/2008, B/Malta/636714/2011 and B/Johannesburg/3964/2012. These observations probably relate to the loss of an N-linked carbohydrate site at position 197 of HA1 which is commonly associated with growth of B/Victoria-lineage viruses in hens' eggs, resulting in the exposure of a dominant antigenic site. Sequencing for four of the Hungarian viruses is complete: 05/2013 has retained the glycosylation site (NET), while 07/2013, 23/2013 and 26/2013 have lost it due to amino acid substitution or polymorphism (NEA, NEI and XEX respectively). All test viruses showed a consistent reactivity pattern, with titres close to the homologous titres, for antisera raised against reference viruses genetically closely related to B/Brisbane/60/2008 but propagated in cells; these post-infection ferret antisera were raised against B/Paris/1762/2008, B/Hong Kong/514/2009, B/Odessa/3886/2010 and B/Formosa/V2367/2012.

Phylogenetic analysis of the HA genes of representative B/Victoria-lineage viruses is shown in Figure 3. All the viruses received with collection dates in 2013 from EU/EEA laboratories carried HA genes that fell into genetic clade 1A. The amino acid substitution associated with the separation of clade 1 into clades 1A and 1B, L58P, has no apparent effect on antigenicity. The HAs of recent viruses show few amino acid substitutions compared with B/Brisbane/60/2008.

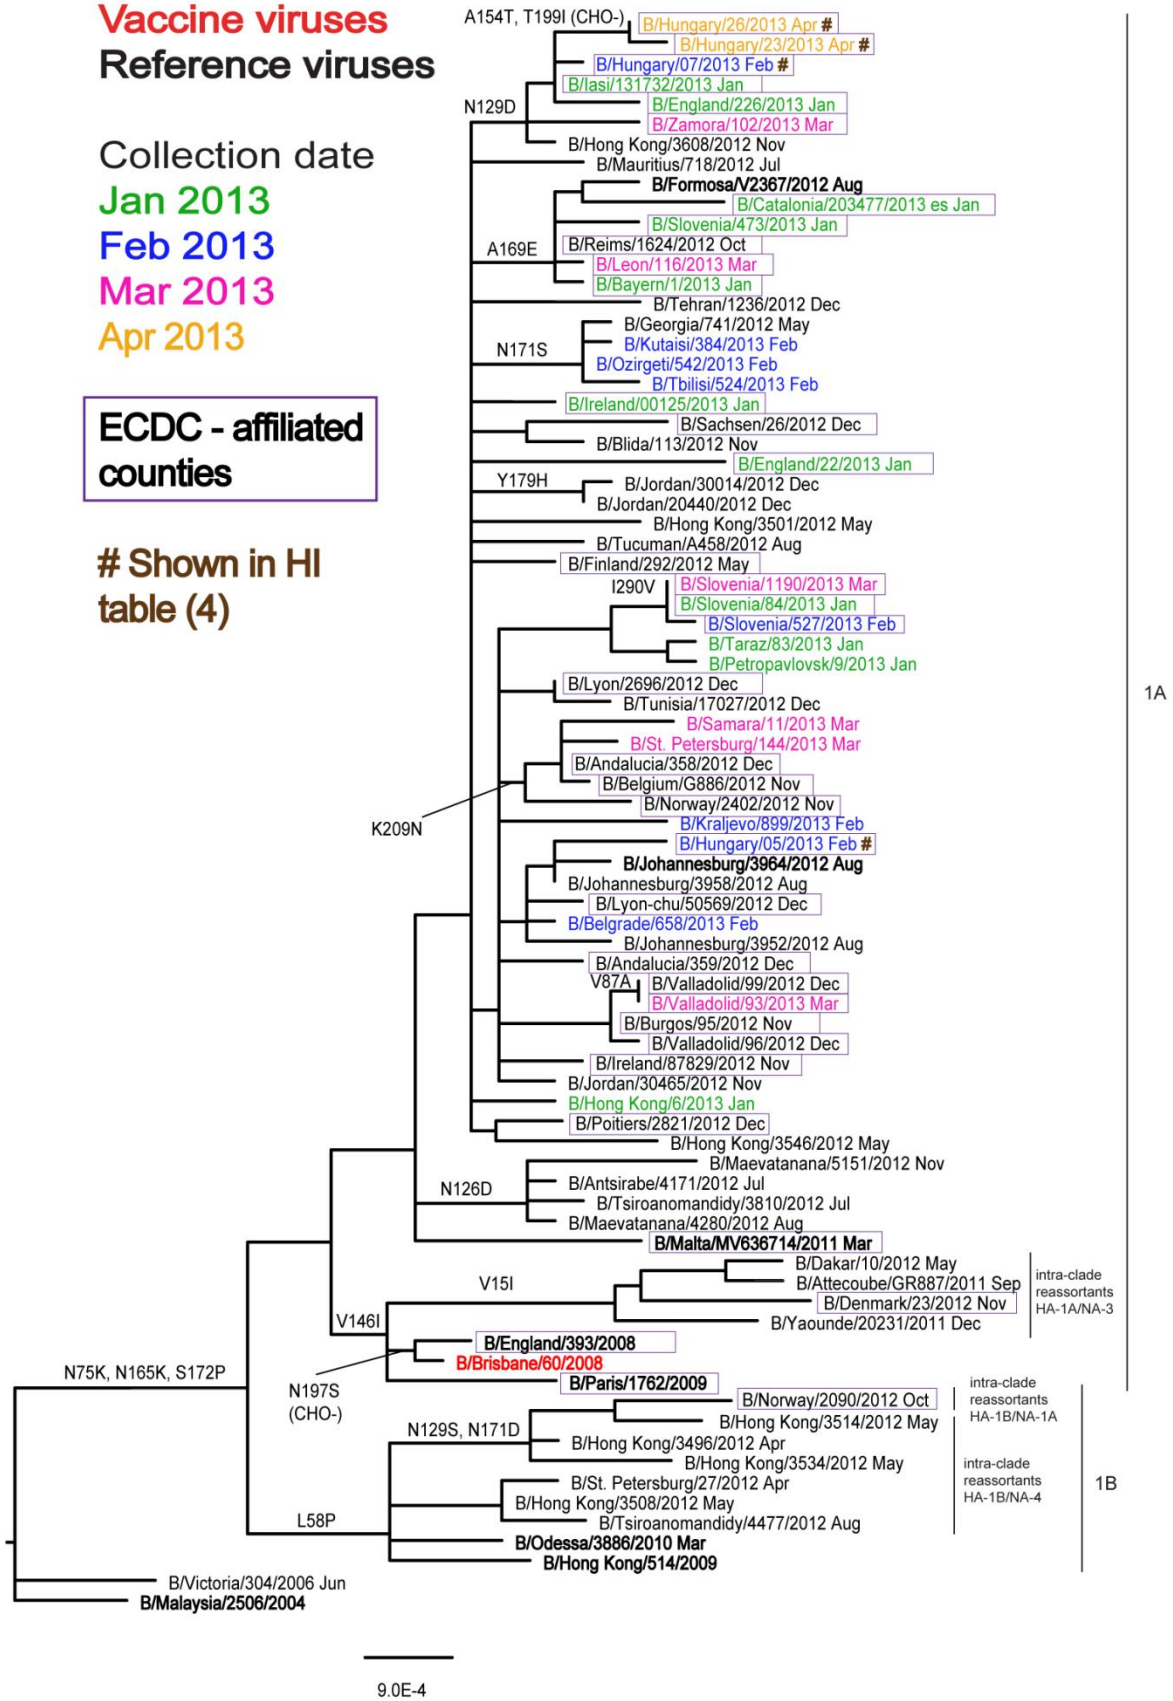
* Recommended B-Victoria lineage component for quadravalent vaccine 2012-13 and 2013-14

Figure 3. Phylogenetic comparison of influenza B/Victoria-lineage HA genes



B/Yamagata-lineage viruses

Table 5 shows the results of HI analyses of B/Yamagata lineage viruses tested since the May report [1]. The genetic clade into which sequenced HA genes of test viruses fall is indicated.

Eleven of 12 test viruses showed good reactivity (within fourfold of the homologous titre) with antisera raised against the egg-propagated vaccine virus recommended for the northern hemisphere winter 2013–14 influenza season [6], B/Massachusetts/02/2012. Antiserum raised against egg-propagated B/Wisconsin/1/2010, the virus used in the vaccine for 2012–13, also showed reactivity within fourfold of the titre against the homologous virus for nine of the test viruses. B/Hungary/22/2013 showed low reactivity with all antisera in the test panel, and in terms of HA sequence its only unusual feature was the loss of a potential N-linked carbohydrate site at position 196 of HA1 (NKT → NKN), compared to the HA sequences of other test viruses. Antisera raised against cell-propagated viruses, whether of clade 2 or clade 3, showed good reactivity (within fourfold of the homologous titre) against the majority of test viruses. Seven of the test viruses had been genetically characterised at the time of preparation of this report, with all falling into genetic group 2.

Figure 4 shows a phylogenetic analysis of the HA genes of representative B/Yamagata-lineage viruses. The analysis shows that the HA genes of recent viruses continue to fall into two genetic clades: clade 3 (represented by the vaccine virus B/Wisconsin/1/2010 and reference viruses B/Stockholm/12/2011 and B/Novosibirsk/1/2012) and clade 2 (represented by the reference viruses B/Brisbane/3/2007, B/Estonia/55669/2011, B/Hong Kong/3577/2012 and the 2013–14 vaccine virus B/Massachusetts/02/2012). The two clades are differentiated by substitutions at HA1 residues 48, 108, 150, 165, 181 and 229. The HA genes of viruses of clade 2 encode **K48**, **A108**, **S150**, **N165**, **A181** and **G229**; the HA genes of viruses in clade 3 encode **R48**, **P108**, **I150**, **Y165**, **T181** and **D229**. The proportion of viruses received with HA genes that fall into clade 2 has continued to increase over the number with HA genes falling into clade 3.

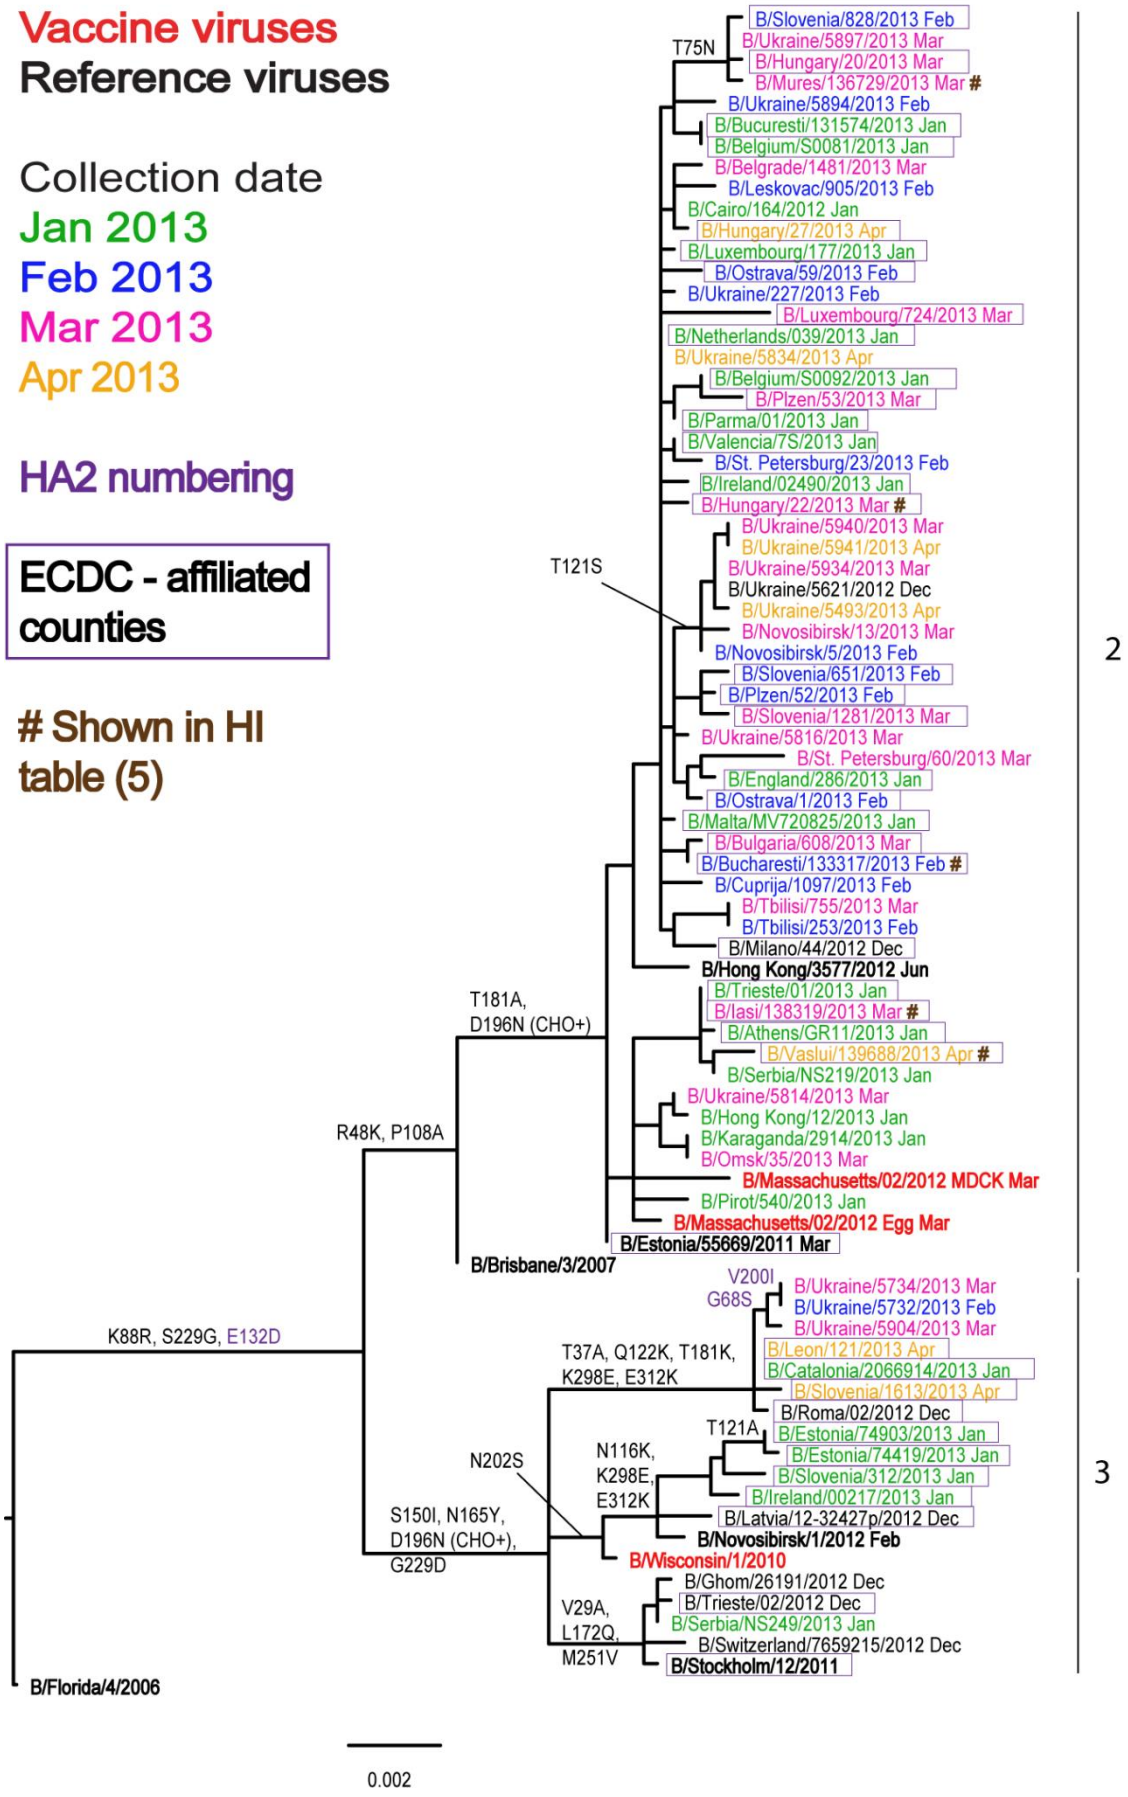
Sequences in phylogenetic analysis (Figure 4)

Figure 4. Phylogenetic comparison of influenza B/Yamagata-lineage HA genes



Influenza A(H7N9) virus

On 1 April 2013, the WHO Global Alert and Response [7] reported that the China Health and Family Planning Commission notified the World Health Organization (WHO) of three cases of human infection with influenza A(H7N9). The cases were confirmed by laboratory testing on 29 March by the Chinese CDC. A description of the characteristics of H7N9 viruses can be found on the WHO website [8]. WHO is updating information on the outbreak regularly [8] and ECDC is posting epidemiological updates [9]. A Rapid Risk Assessment [10] for these A(H7N9) viruses has been carried out and posted by ECDC on 3 April 2013, and an updated risk assessment has been posted by WHO [11]. As of 4 July 2013, WHO reported [12] 133 laboratory confirmed cases and 43 associated fatalities.

A description of results generated by the WHO Collaborating Centre for Reference and Research on Influenza at the MRC National Institute for Medical Research in London, and evaluated at the WHO Vaccine Composition Meetings held in Beijing, China, on 17–19 September 2012 and at WHO Geneva on 18–20 February 2013, can be found at:
http://www.nimr.mrc.ac.uk/documents/about/Interim_Report_September_2012_2.pdf [14]

http://www.nimr.mrc.ac.uk/documents/about/Interim_Report_February 2013.pdf [15]

Note on the figures

The phylogenetic trees were constructed using RAxML and drawn using *FigTree*. The bars indicate the proportion of nucleotide changes between sequences. Reference strains are viruses to which post-infection ferret antisera have been raised. The colours indicate the month of sample collection. Isolates from WHO NICs in ECDC countries are highlighted within boxes. Sequences for some of the viruses from non-EU/EEA countries were recovered from GISAID. We acknowledge all laboratories who submitted sequences directly to the London WHO Collaborating Centre.
